THE "PRIMITIVE PHYSIC" OF REV. JOHN WESLEY

A PICTURE OF EIGHTEENTH CENTURY MEDICINE

GEORGE DOCK, M.D.

ST. LOUIS

Such is the general recognition of the character and eds of John Wesley that the prophecy of his sarstic biographer, Robert Southey, has come true. uthey said:

> Chere may come a time when the name Wesley will be re generally known and in remoter regions of the globe n those of Frederic and Catherine. For the works of such n [as Luther, Loyola, Wesley] survive them and con- ue to operate when nothing remains of wordly ambition the *memory of its* vanity and its guilt.

On the other hand, the little volume on domestic edicine entitled "Primitive Physic" that Wesley him- f thought was the best of his many books, is now nost forgotten. Having picked up a copy recently, a hurried reading I was so strongly impressed with strange combination of good sense and supersti- n in it, that I read it carefully and learned some- ing of the conditions under which it was composed. believe the analysis of such a work may have not ly an interest in recalling an almost forgotten period medicine, but also some value as an index of more dern conditions. A medical book of any early period likely to be interesting, particularly so when, as in e case of Wesley, the author is a *man of* superior ind and influence who lived at a time and in a state culture of cardinal importance.

This is not the place for a full account of the long d *active life of the "awakener of the English con-* th " but some facts should be known in connec- Vesle, qu the medical book that is my chief interest. cation. v was no common man, either in his birth ct, with His father had a superior, even brilliant, m with the ime traits that have justified a com- nded from a Vicar of Wakefield. The mother, at this distance, ne of intellectuals, had an austere of her nineteen fascinating personality, and sev- directed on origi hildren, whose early educations s. John Wesley ea al lines, were gifted in many fortunate in obta rly showed a love of study and al range, both in ex ning an education beyond the that day. Habits tent and accuracy, in the Oxford ysical and menta of hard study and of constant ver relaxed until activity, formed in early life, gure, able to ada his death. Handsome in face and the same time, t himself to all kinds of people, but lomineering and selfish, absolutely fearless in every kind of danger, he had enough of human weakness to make him a thoroughly sympathetic character for a biographer.

At a comparatively early age, while an undergraduate at Oxford, his attention was drawn to medicine. Having read the work on "Health and Long Life" by the celebrated Doctor George Cheyne, Wesley arranged his habits in accordance with the advice he found there, as well as in other medical works of either a popular or a technical character. Quite likely, as Southey said, he collected old women's nostrums. His interest in the care of the body in health and disease was unremitting. About a year before his book was published, with the assistance of an apothecary and a surgeon, he opened a dispensary in Bristol which was so successful that he followed it with others in Newcastle and London, combined with arrangements for the free treatment of the sick in their homes. On the discovery of electricity, he took a keen interest in the application of that force, in its then simple manifestations, to the treatment of disease. He bought a machine and appointed hours when those interested might try its virtues. Thousands, he thought, did so with great benefit.

In 1747, at the age of 44 years, he published "Primitive Physic." Twenty-three editions appeared during Wesley's lifetime, and the thirty-second and last London edition in 1828. My copy is one of the twenty-ninth London edition and is entitled:

"Primitive Physic:/ or/ an easy, and natural method/ of/ curing most diseases/ By the/ Rev. John Wesley, A. M./ Late Fellow of Lincoln College, Oxford./ *Homo sum; humani nihil a me alienum puto.*/ The Twenty-ninth Edition/ London/ Printed by Thomas Cordeux;/ Sold by T. Blanshard, 14 City-Road, and 66 Paternoster-Row./ 1820."

The preface is dated London, June 11, 1747. There are postscripts dated Bristol, Oct. 16, 1755; London, Nov. 10, 1760, and Otley, April 20, 1780.

According to the Index Catalogue of the Surgeon General's Library, no less than seven editions were published in America between 1764 and 1839, several of them combined with other works on domestic medicine. The latest combined with Wesley's the works of T. E Ware and Samuel Thompson, the latter well known as the "steam doctor."

It is certain that Wesley made, as he says in his prefaces, many revisions. Nevertheless, my copy shows many evidences of careless proof-reading, one of the most startling being the heading "200. A broken shin," which was remarked by Hawes in a criticism of the sixteenth edition, and which proves to mean a broken skin. It is possible that Wesley's habitual use of shorthand made him careless. The text gives many evidences of reformed spelling, as "t" for the suffix "ed." I assume that no revision took place after Wesley's death, so that although my copy is a very late one, it can serve as a source. The book is a duodecimo; the printed page measures 13.9 by 7.1 cm.; the pages number 12, 13-108.

The preface begins with a sort of creed agreeing closely with the Miltonian cosmogony, and stating that in the beginning of the human race there was no place for physic. "As man knew no sin, so he knew no pain, no sickness, weakness or bodily disorder. The habitation wherein the angelic mind, the *Divinae Particula Aurae* abode, although originally formed out of the dust of the earth, was liable to no decay, and there was nothing without to injure it." Now, on the contrary, "the seeds of wickedness and pain, of sickness and death, are lodged in our inmost substance; whence a thousand disorders continually spring, even without the aid of external violence," and "increased by everything around us." "The sun and the moon shed unwholesome influences from above; the earth exhales poisonous damps from beneath; the air that surrounds us is replete with shafts of death; the food we eat saps the foundation of life." To lessen these inconveniences, to prevent pain and sickness, we must follow the command "in the sweat of thy face shalt thou eat bread." Exercise and temperance, even without strict adherence to "bread or the herb of the field, go far to preserve us." Then comes an account of the development of empirical medicine, illustrated by the American Indians, whose manners and customs the author had had an opportunity of learning when a missionary in Georgia in his early manhood. Although Wesley had been disillusioned as regards the religious ideas of Indians, he held the conventional eighteenth century view of their medical knowledge, saying that their medicines were quick as well as infallible. He also refers to the traditional Cretan stag (should it not be goat, as related in the fable of Melampus, and the discovery of the cathartic action of hellebore?) and the Egyptian ibis with its invention of the clyster. In short: "Experience and Physic grew up together." "The European" [and he might have gone back to the ancient Babylonian] "as well as the American said to his neighbor, 'Are you sick? Drink the juice of this herb and your sickness will be at an end.'"

Later, said Wesley, came the philosophical age. "Men asked how they might account for these things. They examined the human body and its functions, as well as other animals, vegetables and minerals. Thus physic became inverted; hypothesis took the place of experience and experiment. Also simple medicines were disregarded and even forgotten, and those remote from common observation were used," and "at length physic became an abstruse science, quite out of the reach of ordinary men." Admiration and profit as well as honor attended physicians, who increased the difficulties of their art in order to keep the bulk of mankind at a distance. Technical terms were increased. The knowledge of anatomy, even astrology, was insisted on. Compound medicines were introduced, "containing so many ingredients it was scarce possible for common people to know which it was wrought the cure"; exotics, neither the nature or names of which their own countrymen understood; "yea, and of dangerous ones." But from time to time exceptions occurred, "particularly the great and good Doctor Sydenham and his pupil, Doctor Dover" (whose book, "The Ancient Physician's Legacy" first appeared in 1732). "And some such may be found in the writings of the learned and ingenious Doctor Cheyne, who, doubtless, would have communicated many more to the world, but for the melancholy reason he gave one of his friends, that prest him with some passages in his works which too much countenanced the modern practice, 'O sir, we must do something to oblige the Faculty, or they will tear us to pieces.'"

Wesley then gave his reasons for preparing the book, having consulted only experience, common sense and the common interest of mankind. He thought most diseases could be treated as he describes, thereby saving fortunes otherwise spent on physicians or "pining away, through the ignorance or dishonesty of physicians." Books there are already, he admits, but "too dear for poor men to buy, and too hard for plain men to understand," and in these are too many dear and far-fetched medicines; many dangerous, and consisting of too many ingredients; a thing that "can never be reconciled to common sense." "Experience shows that one thing will cure most diseases, at least, as well as twenty put together. Then why add the other nineteen? Only to swell the apothecary's bill? Nay possibly on purpose to delay the distemper, that the doctor and he may divide the spoil." "Nor are so many medicines needed for correcting each other."

Wesley's idea of the use of the book is naive enough. "As soon as you know your distemper (which is very easy, unless in a complication of disorders, and then you would do well to apply to a physician that fears God), take the first remedy indicated, or if it cannot be had, another. If the first does not give the desired result, use the second, third, and so on. The remedy that cures one man will not cure another of the same disorder, nor the same man all the time." Some remedies he termed "infallible."

In all cases he advised exactness in manner of living, warned against mixed and highly seasoned foods and recommended a sparing diet, only water as a drink, or, "good, clear small beer"; "as much exercise in the open air as possible without weariness, light supper; early to bed and rising betimes." Above all, "that old fashioned medicine, prayer and faith in God." He quoted some rules from Cheyne, and added some forcible words on the advantages of a calm and tranquil mind with the passions kept within bounds, principles that he himself exemplified to a singular degree.

In the postscript of 1755, Wesley speaks of the "swift and large demand for the book; three impressions were called for in five years; it was republished in a neighboring nation and inserted by parts in the public papers." So he revised the whole, "omitting some remedies not so easy to acquire and adding others easy to be had, if not in every home or yard, at least in every town and almost every village in the kingdom." Because they were extremely dangerous he omitted antimony, opium, "the bark," steel and quicksilver, "except in a very few cases." Again he recommended in uncommon or complicated diseases, application without delay to a physician that fears God.

In the preface of 1760 Wesley said he added the word "tried" to those remedies which he found of the greatest efficacy, though he thought many others might be of equal virtue. He also spoke enthusiastically of electricity, "which comes the nearest an universal medicine of any yet known in the world." At the same time he warned against the "substitution evil," which was probably much worse in those days of large and complex draughts than it is now. Twenty years later, In 1780, when he was 77 years old, Wesley issued a revised edition, again commending, in proper cases, the "physician that fears God." "From one who does not, be his fame ever so great, I should expect a curse rather than a blessing." Preferred medicines are now marked with an asterisk.

The text proper is headed "A Collection of Receipts," and consists of paragraphs recommending treatment, arranged under 288 headings in alphabetic order indicating diseases, symptoms and accidental injuries. There are 824 numbered paragraphs, but as there are a few without numbers, and as some paragraphs mention more than one form of treatment, the actual number of "receipts" is fairly large.

The nature of the headings may be gathered from a few. "Abortion, to prevent," comes first, followed by "For an ague," "Canine appetite," "To dissolve coagulated blood," "Hard breasts," "Cancer of the breast," "Children," "Chopt lips," "To prevent the ill effects of cold," "Blood-shot eye," "Pearl in the eye," "Old age," "A consumption," "Corns," "Delivery," "The Plague," "Worms," "Flat worms," "To open a wound that has closed too soon." At the end are a few recipes for various preparations, such as "Daffy's Elixir," a sort of eighteenth century peruna, containing senna, guaiac, liquorice, aniseed, coriander seeds, elecampane root and "raisins of the sun, in the best brandy"; a "more active preparation" contains also jalap and proof spirit or brandy. Turlington's Balsam, James' Powders, Scotch Pills, Emetic Tartar vomit and an eye water are also described. There are then a list of conditions cured by cold bathing, water-drinking, "electrifying" and the use of "fasting spittle," internally and externally. All are advised to buy their medicine at Apothecaries Hall, where "they are sure to have them good."

Much attention is given to general measures, as in Number 1, Abortion: "Women of a weak or relaxed habit should use solid food, avoiding great quantities of tea, and other weak and watery liquors. They should go soon to bed and rise early and take frequent exercise, but avoid being over-fatigued." "Persons who are subject to this complaint should steadily persevere all the year round in the use of the cold bath."

The bath is also recommended for ague, just before the cold fit, followed by the statement "nothing tends more to prolong an ague than indulging a lazy, indolent disposition."

From the section on ague we may learn the spirit of the whole work. Following the general statement just quoted, the patient is advised to take as much exercise as he can bear; to use a light diet, and for common drink, "lemonade is most proper." "4. Or take a handful of groundsel, shred it small, put it in a paper bag four inches square, pricking the side which is next the skin full of holes. Cover this with a thin linen and wear it on the pit of the stomach, renewing it two hours before the fit. Tried." "5. Or, apply to the stomach a large onion, split." "6. Or, melt two pennyworth of frankincense, spread it on linen, grate a nutmeg on it, cover it with linen and hang this bag on the pit of the stomach. I have never yet known it to fail." Other remedies are: yarrow; a drink of cold water followed by a sweat; "9, Or, make six middling pills of cobweb, take one a little before the cold fit; two a little before the next fit (suppose the next day), the other three, if need be, a little before the third fit. This seldom fails." Then, again, we find recommended salt of tartar (potassium carb.), sal prunella, camomile flowers, spirits of hartshorn, a small lemon, rind and all; 8 to 10 drops of laudanum or hiera picra; a waistcoat in which cinchona bark is quilted; a plaster of treacle and soot to each wrist, chicory water, wall flowers, beating together leaves and flowers with salt and applying to the sutures of the head; turpentine on the small of the back, vomiting with ipecac or saffron in wine.

The following are selected to illustrate the remainder of the book: "89, For hard breasts. Apply turnips roasted till soft, then mashed and mixed with a little oil of roses." "91, For a bruise, * Immediately apply treacle spread on brown paper. Tried." "92, Or, apply a plaster of chopt parsley mixt with butter." "93, *Electrify the part. This is the quickest cure of all." For burns, lime water and sweet oil "in the thickness of cream" is said to be the most effectual application the author ever met with. This is the well-known carron oil, or linimentum calcis, U. S. P., as directed by the British Pharmacopeia. A cancer of the breast of thirteen years' standing is said to have been cured by frequently applying "red poppy water, plantane, and rose water mixed with honey of roses." "107. If it be not broke, apply a piece of sheet lead, beat very thin and pricked full of pin-holes, for days or weeks, to the whole breast." Another remedy is "quicksilver and aqua sulphurata," which "has cured one far advanced in years." "Doctor Cheyne says a total asses' milk diet, about two quarts a day, without other food or drink, will cure a confirmed cancer." For "cholic in children," among other things a small teaspoonful of tartar emetic, one grain to four ounces of water," "will puke a child a week old; a large teaspoonful for a month old and so on in proportion. Repeat the puke every day, or every other day, as required."

Sixteen methods are recommended for dropsy, such as dock leaves bound around the joints and feet, inhaling the smoke of amber and vinegar on a burnt brick, or dwarf-elder tea, "which works by urine," and cures a dropsy in twelve hours' time. For sciatica, "boiled nettle poultice has been known to cure after 45 years' standing."

Wesley used physical means with great enthusiasm. He mentions massaging the abdomen an hour a day for dropsy, salt rubs for the apparently drowned, massage for earache and headache; for the breasts, after steaming, "to resolve coagulated milk," and for flabby swellings, followed by a proper bandage. "To kill the animalculae that cause the gums to waste away from the teeth" he recommends gargles of salt water. He advised change of air in whooping-cough, bleeding for menorrhagia and in plague—50 to 60 ounces for the latter.

External methods of treatment vary from the simplest to the strangest or most absurd; from lime-water and olive-oil in burns, or turnip poultices for hard breasts, to soot and treacle for ague, hogs' lard to the feet for whooping-cough, scraped peony to the feet for convulsions, rotten apple poultices for inflamed eyes. (He warned against bread poultices over inflamed eyes.)

He recommended issues, then in great repute, for asthma and to cure quinsy, for the latter placing the issue in the thigh. His ideas on clothing were sensible, advising against the roller for infants, and commending the flannel binder for colic. Clysters he used sparingly, as for apoplexy, butter and salt, laudanum for hysteric colic, and cold water with woodbine in fevers.

He gave suggestions about diet, including such things as prunes for constipation (used by the Romans), whole wheat bread—long before Graham—for the same; bread crusts for dropsy; vegetables for obesity; oysters, four or five, for heart-burn; withholding meat from children under 2 years and tea before 12. Milk he often recommended, as in the treatment of asthma, epilepsy, consumption and whooping-cough.

Charms, amulets and other strange or occult methods are numerous and varied. I have noted about seventy, a small proportion of which only can be quoted. There is a little roll of white paper placed under the tongue for nose-bleed; a sheet of lead (mentioned before) to be worn for days or weeks over a cancer of the breast; powdered horse-spurs ("warts that grow on the inside of the horses' fore legs") in ale, for the same, or goose-dung and celandine externally; "or blow the ashes of scarlet cloth into the mouth or throat for cancer of the mouth. It seldom fails." This is also used for thrush. For consumption, "take a cow-heel from the tripe house, ready drest, two quarts of new milk, two ounces each of hartshorn shavings and isinglass, a quarter of a pound of sugar candy and a race [root] of ginger; put all of these in a pot and set them in an oven after the bread is drawn. Let it continue there until the oven is nearly cold; and let the patient live on this. I have known this to cure a deep consumption more than once." Cow's heel broth is also recommended externally for restoring strength after rheumatism. "184, Or, every morning cut a little turf of fresh earth, and lying down breathe into the hole for a quarter of an hour. I have known a deep consumption cured thus." "191, In the last stages, suck a healthy woman daily. This cured my father." [In the twenty-sixth New York edition, according to Plummer, *Nashville Journal of Medicine and Surgery,* October, 1858: "tried by my father."] For cramp he advised tying the garter tight under the knee; or "hold a roll of brimstone in the hand. I have frequently done this with success." For films on the eyes: "dry zibethum occidentale, i. e., stercus humanum, slowly, powder it fine and blow it into the eye twice or thrice a day." For hot or sharp humors, "lap a thin slice of raw beef on the nape of the neck. Tried." For white specks in the eye, "going to bed put a little ear wax on the speck. This has cured many." For epilepsy many methods are advised, as "blow tobacco smoke down the throat."

Metallotherapy is anticipated by saying, "One who is subject to the falling sickness may prevent the fit if he feel it coming on, by this simple expedient. Let him always carry a piece of metal as broad as he is able to hold between his teeth when his jaws are stretched to the utmost. When he feels the fit approaching, let him immediately put this between his teeth so as to keep his jaws at their utmost stretch. In about a minute this will bring him quite to himself and prevent the fit for that time." "Or, in the fit, a similar maneuver by a bystander will stop the fit." For gout, "apply a raw lean beefsteak. Tried." For iliac passion, "hold a live puppy constantly on the belly. (Dr. Sydenham)." "For pleurisy take half a drachm of soot." Warm cow-dung spread on leather, with cumin, is advised for "windy rupture"; "it commonly cures in two days." "Rubbing with fasting spittle" is recommended for shrunken sinews: "Tried." "To stop vomiting apply a large onion split across the grain to the pit of the stomach, Tried." "For relaxed uvula, bruise the veins of a cabbage leaf and lay it hot on the crown of the head; repeat if needed, in two hours. I never knew it to fail." For a whitlow a poultice of chewed bread is recommended.

To one not familiar with medical practice in the eighteenth century, these trivial, absurd or disgusting remedies seem impossible for a man of Wesley's education and knowledge, in an age after Bacon, Harvey, Locke, Sydenham and Newton and in the century of Hume, Voltaire and Franklin, in the period of the Encyclopédie, the "Wealth of Nations" and the "Social Contract." Those who recall the practice of Wesley's contemporaries, or who investigate it, will come to a different conclusion. Let us consider the period and the medical ideas during the time in which Wesley lived, leaving out of consideration the fact that he was a theologian, because we may see that that had little to do with the case. He was a man of wide reading and contact with all kinds of people and had a mind open to many topics. His life almost filled the eighteenth century, June 17, 1703, to March 2, 1791; a century that proved epoch-making for England's political greatness and literary preeminence. The essay and the modern novel began then with great brilliancy; Shakespeare became permanently established as the greatest figure in English literature, while a galaxy of other immortals left their impress on prose and poetry. Blenheim was fought the year after Wesley was born, the Battle of the Nile the year in which he died. Although it has been called the age of enlightenment, it has also been aptly called the "Cinderella of Centuries," and in regard to social and intellectual conditions the reproach is only too well deserved. The Revolution, which brought in a new, and, in many respects, liberal government, did little to elevate intellectual development, encouraged hardly at all by the Puritans. Newton enriched physics and gave a stimulus for future investigations, but his immediate effect on medicine was chiefly the strengthening of crude mechanical theories. During the Civil War and under the Restoration quackery reached a degree of boldness and rapacity never known before, and probably not since.

The microscopic discoveries of Leeuwenhoek in the end of the seventeenth century were not followed up very actively during the whole of the eighteenth century. In practical medicine the objective clinical observations and relatively sober therapeutic methods of Sydenham made hardly any impression until after Wesley's death, when the great French school of Corvisart, Bichat, Bayle and Laennec began the real medical renaissance. The fact that Wesley commends Sydenham and his disciple, Dover, the buccaneer and inventor of Dover's powder, is of more than passing interest, for Sydenham has always been one of those more talked about than read, more praised than studied, and while the great masters of medicine al joined in lauding Sydenham, the rank and file of th profession were almost wholly uninfluenced by hi methods, but continued, as Locke said, in "the romanc way of physic." There were some extenuating circumstances. Sydenham praised the clinical methods o Hippocrates, but so did every system-maker who flourished in the long centuries of system-making. H lauded accurate observations and well-founded deductions, and his clinical pictures are often models of clearness, but also often so loaded with theories that it is tiresome to read them now. If he deserves credit for recognizing the importance of morbid processes, he did much to continue the error of the personification of diseases. Though he praised objective delineation of clinical conditions, he assisted in fixing the idea of species in disease, like those in botany. His view that the Creator had placed remedies in every land that act as specifics in every important disease, was quite as harmful as the older theories and has weighed down medicine even to our time. I shall give some examples showing that his methods in therapeutics hardly deserved Wesley's praise.

Of Sydenham's followers, one of the most renowned was Boerhaave. He improved on Sydenham in the fulness and accuracy of his clinical pictures, and made a great advance by his efforts to associate the anatomic changes with the symptoms. His therapeutics were immensely ahead of his time, for he taught principles and rarely gave formal prescriptions, but it is more than probable he could not be understood by many of his contemporaries. This is the main reason why he is known chiefly through Van Swieten and Haller, his most brilliant pupils. The former deserves credit for the stimulus he gave to clinical teaching in Vienna, but this only became effectual late in the century, and the same is true of the physiologic innovations of Haller.

In England the names of Pitcairn, Pringle, Cheyne, Morton, Huxham, Mead, Cullen and Brown are the most conspicuous before and during Wesley's time, and they are read now only by students of medical history. Some of them I shall have to quote. A few more names and dates will make Wesley's medical and biologic environment plainer than any detailed explanation.

John Hunter, the greatest mind of the period, was twenty-five years younger than Wesley, and outlived him two years. Morgagni was twenty-two years older; his great work on the "Seats and Causes of Disease" did not appear until 1761, and although in time it helped to destroy the dogmas that had so shackled medicine before that, the effect on the practice of the time was slight. Peyer, Leeuwenhoek, Leibnitz and Mead were older. Haller was five years younger, Lieberkühn, Van Swieten, J. F. Meckel senior, Senac, Casper Friedrich Wolff, Linnaeus, Auenbrugger, John Brown and Huxham were almost contemporaneous. Priestley, Vicq d'Azyr (1748-94), Sömmering, Cuvier and Galvani were born when he was middle-aged or later. Lavoisier was guillotined three years after Wesley's death, and Jenner made his first experiments with cow-pox two years later. Bichat was not born until Wesley was nearly three score and ten. The public teaching of anatomy in England began in the early part of the eighteenth century. Inoculation was introduced into England when Wesley was 18. Electricity was discovered in 1745, when Wesley was 42. Black discovered carbon dioxid in 1750. Cavendish made his observations on air when Wesley was over 60, and made water from gas when he was almost 80. The use of digitalis was not made known by Withering till Wesley was 72 years old.

Wesley's attitude toward medicine was, of course, to be explained partly by general mental traits, and one of his most pronounced characteristics was a deep-seated credulity. As a child he experienced the ghost episode in his father's rectory, so fully related by all his biographers, and he always inclined to a supernatural explanation for it, though his brother Samuel shrewdly suggested that while "wisdom found no explanation, wit might find many" for the ghostly knockings. He recommended in general the habit of suspending judgment as a safeguard against hasty decisions, but Lecky is perhaps right in saying he was utterly incapable of that function. He believed in the claim of Elizabeth Hobson, of seeing her neighbors just before or at their deaths and in a celebrated prediction of the end of the world. He believed in witches, thinking that to doubt them would be to disagree with the authority of the Bible, but in Wesley's time many people little influenced by the Bible believed in witches. Several witches were executed in Wesley's childhood; the last, in Scotland, was burnt in a pitch barrel in 1727 when Wesley was a Fellow of Lincoln College. After the earthquake in Lisbon in 1755 the London theaters were closed for a time out of fear of a similar judgment.

Wesley was curious and inquisitive, but was a better logician than observer, like many in his time, and it was a time when reasoning was valued much more highly than accurate observation. As Lecky says, Wesley had an exaggerated passion for reasoning, but neglected premises.

Some of the great delusions of the middle ages still flourished. Belief in the healing power of the royal touch for scrofula was stronger after the Restoration than ever before, and the prayer used in the ceremony was inserted in the Prayer Book in the time of Queen Anne and repeated in that of George I. Samuel Johnston was "touched" in 1712. Not only great divines, but surgeons of reputation testified to the reality of the cures. Ridicule did not shake it. In France other gifts of Louis XIV gave rise to a parody on the formula: "Dieu te guerisse, le Roy te touche" —"God save you, the King has kissed you," but the custom was kept up in France until 1825, and even later, in remote parts of Scotland, coins with the effigy of Charles I were supposed to carry the miraculous power.

Let us analyze some of Wesley's medical methods and views more in detail. Taking first materia medica, he used about 160 drugs. All of them and more were used by Sydenham, and particularly many that are now obsolete. Seventy-eight, or nearly half, are still in the U. S. Pharmacopeia. Eleven others were formerly there, most of them up to 1890 (valid to 1903) and forty more are mentioned in the second part of the U. S. Dispensatory (1907). Most of the official drugs used by Wesley are completely ignored by leading physicians now, and he rarely used the more potent drugs. So we find asafetida mentioned only once, for insomnia, "as good as opium"; aloes, arsenic (for cancer of the breast, internally), cantharides (for diabetes), digitalis (for white swellings), male-fern (for worms), each once only. Tincture of iron is used only on tents, for nose-bleed, but steel filings, official in the U. S. P. in 1850, is recommended for green-sickness, and forge-water for mouth wash with alum. Laudanum, aside from its use in ague, is recommended for colic, in clysters, in epilepsy, and for quinsy, at night. On the other hand, tar-water is recommended for twelve conditions, including old age. (Bishop Berkeley, who made tar-water famous, was earlier than Wesley.) Burdock root and seed are recommended eight times for various conditions, from colic to leprosy; nettles are used for eleven conditions, from hemoptysis to sores ("any old sore" as Wesley, with a modern touch, puts it), or nettle stings.

It is interesting to compare Wesley's treatment with that of some of his contemporaries and I begin with one whose works had great influence during the latter half of the eighteenth century. Frederic Hoffmann was more than forty years older than Wesley, and lived until the latter was almost 40. He was a man of extraordinary industry and corresponding influence. According to him, reason and experience were the foundations of medicine, which in time would become a science through the aid of physics and anatomy. His mechanical theories gave the characteristic features of his system and long affected the views of the profession. He deserves credit for popularizing the use of mineral waters, and one of his mixtures, well known as Hoffmann's anodyne, is still prescribed. Guided by his view of pathology, he made extensive use of antispasmodics, sedatives and evacuants.

In tertian fever Hoffmann vomited with ipecacuanha or tartar emetic; he thought repeated attacks of intense heat may dispose the stomach to inflammation and therefore endeavored to lessen the fever. Purging salts may be substituted for, precede, or be combined with, emetics, or if there is great weakness or sensibility of the stomach, emollient and carminative clysters and gentle laxatives, manna, rhubarb, sal diureticum (Potas acetas) and some aromatic oil are to be used. "The next indication is to strengthen the solids, particularly the stomach and intestines; and of all the known astringents or corroborants, Peruvian bark is the most successful; given in the time of intermission in doses of about half a dram every four hours." "It raises the pulse and spirits and increases perspiration in choleric persons, loosens the belly and by these marks discovers its salutary operation." After the fever has been removed, the bark must be continued with elixir of vitriol, bitters and some stomachics. Niter, sal ammoniac or alkalines may be added to the bark in certain cases. Venesection is proper and an infusion of chamomile flowers is to be drunk some hours before or after. "In obstinate tertians, as autumnal ones generally are, and those which have degenerated in quotidians, antifebrile draught composed of simple waters, salt of wormwood and spirit of vitriol, exactly neutralized, is of eminent service." Hoffmann opposed opiates in malaria, against the authority of Sydenham and Lind.

The history of a case is instructive, in showing the overdosing and the long course of the disease. "The hot fits continued six hours. During the third paroxysm, saline nitrous juleps were given at intervals; the crisis promoted by an infusion of scordium (alliaria off.) and lemon peel; and niter with sal diureticum given in the intermission." These medicines were continued until the ninth paroxysm, when "the symptoms being much mitigated, the patient was purged with manna and sal polychrest (saltpeter and sulphur), the fever stopped by an electuary of bark and the cure confirmed by balsamic peels and an aperient saline powder."

For hemoptysis, Hoffmann advised a mixture as a decoction in ale, of daisies, red roses, chamomile flowers, milfoil (*Achillea,* U. S. P. 1870) tops, saracens, comfrey, ground ivy, dead nettle, veronica, sanicula, wintergreen, fennel, fennel seeds and nutmeg.

For consumption he recommended milk; that of the ass on account of its "sweet detergent serum"; "for healing lacerated parts, goats' milk will suffice; and for repairing the wastes of flesh and strength, nothing can exceed human milk, sucked immediately from the breast." "The virtues both of milk and whey can be improved by feeding the animal on pectoral plants."

For cleansing and healing pulmonary ulcers, the best balsam is composed of copaiba, myrrh, saffron, aromatic oils, opium, oil of almond, spermaceti, honey and wax.

"As phthisis frequently proceeds from translation of acrimonious humors to the lungs, the revulsion and evacuation of chest humors may be attempted by issues in the neck and between the shoulders."

For iliac passion Hoffmann quoted Hippocrates' method, and went on to give anodynes and carminatives, or if these fail, a pound of quicksilver.

For skin diseases, he used baths with slag, but looked on bleeding as the chief remedy, even in the itch, and held that external remedies should always be the last, and not used until blood and humors were purified.

Another influential author in Wesley's early life was Richard Morton, whose works on consumption, fevers and other diseases were held in high repute for a long time. In the treatment of consumption of the lungs, Morton advised bleeding, followed by a "gentle vomit" of honey of squills; "yea, and sometimes crocus metallorum (antimony), after which opiates are to be used, such as cordial milk water, carduus water, barley-cinnamon water and white poppies." Purges are to be added, like senna, cassia, tamarinds, coriander seed, manna and sal prunella. A sleeping medicine is to be given, such as rose, aloes and houndstongue pills, gilt, given every other night "after the patient has been blooded," besides diaphoretic and sudorific medicines and vesicatories to the arms and shoulders. "We must not by any means neglect the frequent use of those medicines commonly called pectoral or pulmonary, which must be used very plentifully, as it were in the manner of a diet, but always in such a form as is most grateful to the patient. For these we may take sugar candy, sugar of roses, or black lozenges for a cough, which must be often and gently swallowed. Butter, buttered ale, linseed oil, raisins and figs may be used; a "neat form" of expectorant is the following: "Oil of fresh almonds, syrup of comfrey, red poppies or dried roses, syrup of meconium—an opium preparation—and sugar of roses, or lohock of foxes' lungs, colt's foot, purslane, syrup of jujubes, maiden-hair, flower of brimstone, tincture of saffron, cold species of tragacanth, of pearl, Haly's powder, saccharum peridiatum." There are many pages of such prescriptions, one containing powder of wood-lice. It may be supposed that the lohock of foxes' lung is a vegetable remedy, but this is not so, the lungs of real foxes, killed in hunting, being used.

The celebrated Huxham gave one of the most accurate of the early descriptions of typhoid fever. He also had the sagacious view that bleeding was not useful in that disease. What he recommended was a blister behind the ear, "a gentle emetic" and "an easy clyster." "Blisters," he says, "are useful at all times of the disease, for by them the oscillatory motion of the vessels is promoted and the subtle salt of the cantharides incides the viscid humors, and at length expels them."

He further advised "attenuants which greatly irritate the nervous fibrillae," such as cinnabar, sulphur, galbanum and asafetida. Large quantities of simple cold water he considered harmful, but Peruvian bark, snake root, elixir of vitriol, tincture of roses, mulled wine, etc., are all advised.

Huxham also studied lead colic and treated it rather more actively than Wesley. He gave a vomit of ipecacuanha, sal absynth and chamomile flowers, to which tartar emetic may be added, followed with purges with opium and calomel, and later by milder cathartics like rhubarb.

Let me quote from Sydenham himself to show the examples Wesley had. I gave Wesley's treatment for iliac passion, which included, in the fashion of the time, various forms of intestinal obstruction. Among other things, he mentioned the use of a live puppy and referred to Sydenham.

In the treatment of that form of ileus due to irritation with inverted action of the peristaltic movement, the English Hippocrates rejected bullets and quicksilver. He began with salts of wormwood in lemon juice night and morning, with sweetened mint water between, and a "live puppy kept continually lying on the naked belly." Two or three days after the pain from vomiting had wholly ceased, he gave a drachm of Pil. coch. maj. in mint water. "The puppy is not to be taken off before the patient begins with the pills." The pill mentioned contains:

French hiera picra	ʒ x
Lozenges of alhandal (colocynth)	℥ iiss
Scammony	ʒ iiss
Gummy turbeth (mercuric subsulphate) French lavender, āā	ʒ v
Syrup of French lavender	q. s.

[Hiera picra was made of cinnamon, lignum aloes, asarum root, spikenard, mastich, saffron, aloes unwashed, and honey.]

When we see Sydenham using such mixtures and many others containing from three to five dozen ingredients, we understand the practical result of his theories. "A murderous array of diseases has to be fought against," he said, "and the battle is not a battle for the sluggard."

There is an interesting example of Wesley's scholarship in the reference to the use of a live puppy. In Latham's translation of Sydenham's works, published by the Sydenham Society, a "live kitten" is specified. In Kühns' Latin edition, as well as in Greenhill's, used by Latham, the word is *"catulum."* Now *catulus* means in general the young of any animal, but especially a puppy, as shown by illustrations in Harper's Latin Dictionary. Mead, a contemporary of Wesley, quoted this use of a puppy with approbation.

As Sydenham's therapeutic methods were relatively simple, as compared with the prevailing practice, we can understand Wesley's advance in the same direction. His care for the purses of the sick can be understood by the complicated mixtures then, and much later, in use. Dover gives the actual figures by saying he "could never bring an apothecary's bill to three pounds in a fever; whereas some of their bills in this disease amount to forty, fifty and sixty pounds."

Boerhaave, nearer to Wesley's time, and in many respects more modern in his treatment than Sydenham, used methods that make Wesley's look like sheer mental suggestion. For apoplexy he bled, used setons and fly blisters, bandages to the extremities, irritating powders to the nose and pharynx in order to "separate the pituita from the blood in the brain and set free the vital spirits," while internally he gave woodlice and cochineal.

For epilepsy he described, but did not recommend, the use of the blood of strangled gladiators or other men, and used from the time of Arataeus to that of Tulpius, whose face, immortalized by Rembrandt, still ornaments medical schools, though his works are never consulted. He also found it necessary to oppose, in the eighteenth century, the use of human livers, the brains of children or the skulls of men dead from violence, saying that what was needed was medicinal aid and not human sacrifices.

That Wesley was no mere collector of recipes, but had his own ideas on medical topics, appears in many instances among the methods of treatment. So, to prevent catching infectious fevers, he warned against breathing near the face of the sick, or swallowing saliva while in the sick room. Flooding in lying-in is "never to be thought little of." He objected to the common advice not to attempt to cure gout, saying he had cured himself many times. He held that madmen are all cowards and "may be conquered by binding only, without beating," anticipating the reform of Pinel by half a century, and the practice of some American asylums much longer. For the bite of a mad dog, for which he gives several simple remedies, he adds with a "pointer": "Immediately consult an honest physician." He says he was bitten six times by mad dogs and cured by squeezing, bathing and washing the wound for an hour with salt water—a pound to the quart—and binding salt on it for twelve hours. He warned against constipation and against catching cold after measles. A statement never too commonplace is, "When the nerves perform their office languidly, a good air is the first requisite." After giving a mixed herb wine for hernia, he adds that a good truss is of great use and perhaps the only thing to be depended on. Scaldhead in children, he said, would seldom be seen if proper regard were paid to cleanliness in the head and apparel. He asserted there were no worms in teeth, and said that coral was "always useless for children, and often hurtful." To prevent flatworms he advised against drinking stagnant water.

Regarding itch, he said: "This is nothing but a kind of very small lice, which burrow under the skin. Therefore, inward medicines are absolutely needless. Is it possible any physician should be ignorant of this"? He advised strong rum, black soap, sulphur, white hellebore and cream, and lemon juice with oil of roses. The answer to his question is a melancholy one, for the itch has a long and not very creditable history. The Greek, Arab and medieval physicians knew the disease. In the middle ages the insect was known and was supposed to be a louse or a weevil. Thomas Moufet, who died in 1600, gave a description of the mite, which had been seen and described by Joseph Scaliger in 1557, and Bonomo rediscovered it in 1687. A century earlier Roudelet described the operation of extracting the insect with a needle. Bonomo and Cestorio gave a clear account of the relation of the mite to the disease and Linnaeus and de Geer described it zoologically; but Wichmann had to repeat Bonomo's arguments in 1787. Nevertheless, leading physicians through all of this period and almost to the middle of the nineteenth century refused to believe in the etiology and ascribed the itch to acrid humors and morbific blood. Gales mystified the French savants with cheese mites in 1812, and it was not until 1834 that Renucci, a Corsican student who learned from old women in his fatherland how to extract the insects with needles, settled the question in Paris. The male insect was not discovered until 1845, by Kraemer, and Eichstedt a year later first described the eggs in the burrows.

Another interesting evidence of Wesley's advanced point of view is in the frequent use he made, or recommended, of water, internally and externally. In the text he recommends cold baths no less than sixty times, and in the section at the end of the book he gives a summary showing their application to various diseases, from convulsions and insomnia to hydrophobia. The use of baths for the latter—including keeping the patient under water as long as possible—is very old and, of course, baths had been used in medicine long before, but just before or during Wesley's time, they became relatively neglected. Even the enthusiastic reports of Sir John Floyer had little effect on this neglect. Floyer, it will be remembered, introduced the use of the watch in pulse-counting and made important observations on the pulse under various conditions, including its relation to respiration. In 1697 he published "An inquiry into the right use of the hot, cold and temperate baths in England." In 1702 he published his "Psychrolusia," in which he referred the hydriatic treatment of disease to baptism, and ascribed the spread of rickets to the change from baptism by immersion to merely wetting the head. Cheyne and Mead used cold baths and Smith (1721) used them for improving the constitutions of children, and a clergyman, John Hancock, in 1773 recommended them for measles and other fevers. Apparently little influence was exercised by any or all of these writers, while Cullen labored in the profession and Buchan among the laity to extend the use of water, but it is certain that Wesley was aware of their doctrines and preached them with energy. It will be recalled that the proverb "Cleanliness next to Godliness" is his. I think he may have obtained some of his views from the book of Johann Sigmund Hahn, "Die wunderbare Heilkraft des frischen Wassers," Schweidnitz, 1745. It is interesting that Wesley quotes a case related by Floyer without indicating its source, while Hahn gives it more fully, with credit. Wesley makes the brief statement under "A cancer of the breast," "Use the cold bath. (This has cured many.) This cured Mrs. Bates of Leicestershire of cancer of the breast, a consumption, a sciatica and rheumatism, which she had had near twenty years. She bathed daily for a month and drank only water." It is amusing to find that Hawes, one of Wesley's severest critics, doubted the existence of this Mrs. Bates.

Hahn says:

> Mrs. Bates, a woman of 50 years, was consumptive, coughed hard, had pain in the limbs for 20 years, especially sciatica; had immobility and weakness in the knee, sat constantly by the fire, covered with many garments, and could not stand a draft; she had lumbar pain which she thought due to stone and a pain in the breast that was thought to be cancerous. She went to Willowbridge bath, which is very cold, also drank several glasses and so continued for several months. The first time the heart was very painful, later not so much so; with the next bath the pains retracted from the back to the feet, and at last she was perfectly well and without relapse; she walked and ate well, dressed lightly; the stone was gone and also the tumor in the breast. She continued drinking water.

Another case mentioned by both Wesley and Hahn is that of Mrs. Watts, who, by using the cold bath two and twenty times in a month, was entirely cured of an hysteric colic, fits and convulsive motions, continual sweating and vomiting, wandering pains in her limbs and head, with total loss of appetite (164). Hahn describes the patient as weak and hectic. "Medicines and Bath water internally and externally had no effect. She took cold baths in London, bathing every morning, and plunging under water six or seven times before going to bed, and so was cured."

An interesting contrast to Wesley's enthusiasm for water is his extensive use of saliva, especially "fasting spittle," which "outwardly applied relieves or cures blindness, gout, gravel, King's evil, leprosy, palsy, rheumatism, scurvy, stone and swelled liver." This is still in use in Germany, according to Bartels.

In the case of these more extraordinary remedies Wesley was, of course, following old examples, some of which go back to the very beginning of medicine. An instance of this is the "Zibethum occidentale," or stercus humanum, recommended for films over the eyes. Paullini, in the well-known "Heilsame Dreckapotheke," has several chapters devoted to diseases of the eye, such as pain, red and running eyelids and cataract, in which he quotes many contemporaries in such a way as to prove Wesley lacking in appreciation of the world of materia medica literally under his feet.

Another interesting survival is human milk, which was apparently used in wasting diseases in the time of Wesley, though it seems to have been neglected since then.

Wesley's care of his own body is one of the best evidences of his judiciousness in such matters. He is a good example of the truth of the adage: "A man is a fool or a physician at forty." He did not come from a particularly healthy family, and he inherited the family gout. Many of his brothers and sisters died young; he spent his early years in the malarious fen country. Lack of food was no uncommon event in his youth. Nevertheless, he lived to the age of 88 years, and accomplished an amount of physical and mental labor, either of which would be most unusual. Some details of the methods he used to maintain his health, and the work he accomplished, should be considered. He himself ascribed much of his good health to the scheme of life he adopted from Cheyne. Cheyne condemned salt and seasonings, also pork, fish or stall-fed cattle, and recommended for a drink two pints of water and one of wine in twenty-four hours, with 8 ounces of animal and 12 ounces of vegetable food in the same time. Besides what he learned from Cheyne and from the popular medicine of Tissot, Wesley laid stress on his constant exercise and change of air; his never having "lost a night's sleep, sick or well, on land or sea"; "having sleep at command so that he could call it and it came"; to having risen for more than sixty years at 4 a. m., preaching at 5, and having so little pain or sorrow. The account of his early rising is interesting. At one time he was troubled with insomnia, but cured it in the following way: He set back an alarm clock an hour each morning, from seven to four, and when he reached the latter found that he went to sleep at once and slept until four, which he fixed for his rising hour. He was a constant reader, and an indefatigable traveler. He went about much on horseback, reading as he went, and sometimes getting bad falls. At 83 years he traveled 76 miles in a day, and preached three times. At 85 he delivered more than eighty sermons in eight weeks.

Besides gout, which he mentions, he had hemorrhage from the lungs in middle age (50 years), and was advised by Fothergill to stop preaching, but did not. He also had an operation of some kind, and in 1789 had what he called diabetes. At one time he gave up the use of tea, but resumed it again at Fothergill's advice. The strain of preaching to several thousand people in the open air he never seemed to feel. While he weighed but 122 pounds, his voice could be heard at 140 yards, and he was able to rivet the attention of 8,000, 10,000 or even 20,000 people.

Though he was interested in the health of his people, he had no patience with interesting invalids, valued the services of physicians, and treated the numerous examples of religious hysteria that occurred in his congregations with great skill, having the subjects at once removed out of his sight, where, as he said, they became as quiet as lambs.

It is difficult to say how much influence "Primitive Physic" had. Southey thought it was very great and very pernicious. Judging from medical literature and medical practice it does not now seem to have done much good, and probably very little harm, and this is in contrast to what almost all critics have thought of Wesley's other achievements. Leslie Stephens calls him the greatest captain of men of his time. Macaulay thought he had a genius for government not inferior to that of Richelieu. Southey thought his the most influential mind of the century; Lecky, that his religious revival was of greater historical importance than all the splendid victories by land and sea under Pitt. He has been supposed to be the chief force that saved England from such a revolution as that of France. How could the book of such a man, printed in so many editions, fail to make more of a mark?

We are fortunate in having criticisms of Wesley's book by physicians, published in his lifetime, and at widely different periods after that. The first was by a man of prominence, Dr. W. Hawes, one of the founders of the Royal Humane Society. Hawes' work had the laudable object of preventing the public from being imposed on. He criticized many of the remedies for reasons that we should all agree on, and his criticisms probably had something to do with the absence from the later editions of many methods mentioned in the sixteenth, including the use of powdered toad, which Hawes thought suitable to the credulity of the frequenters of the foundry, and of a red-hot poker under the nose. He criticized Wesley's rather frequent use of wine as tending to encourage "dram-drinking," but he shows some faults of his own in asserting that poultices convert "benign hardnesses" into cancer, ascribed cancers to fermentation and thought that the use of cold baths would convert skin eruptions into internal inflammation or fever; that blisters on the feet from walking would dry up over night, and thought it ridiculous to try to relieve thirst in fever by drinking water. To those who compare the present with the good old days, it may seem interesting to find Hawes objecting to Wesley's "hardening" on the ground that "the state of the population is at too low an ebb for the lives of children to be sacrificed to the ignorance of old women or the indolence of nurses."

Hawes throws light on the conditions of the time when he states that fevers carry off one-third of the human species (Sydenham put the loss at two-thirds), and that in fevers the physician should see the patient twice daily.

Almost a century later Dr. John T. Plummer[1] in a keen but kindly article, based on the twenty-sixth American edition, criticized especially the superstitious remedies, like the guts of a serpent, for bites (omitted from the twenty-ninth edition), but excused them as characteristic of the age, and suggested that we might retain some equally futile remedies, so-called. He even thought that Wesley's use of saliva might be justified by Lehmann's chemical investigations, and mentioned the long use of burnt sponge, now known to contain iodin, as an example of correct empirical therapeutics.

Another and more recent criticism[2] appeared in the *British Medical Journal* as an unsigned article, and apparently, having been "tried on the dog" in England was published under the name of Burton G. Thomas,[3] M.D., in the *American Physician*.

This author thinks the work gives "evidence of a hiatus in the mind of Wesley, natural and inevitable in a theologian of that day, and not unfamiliar even in some of the theological intellects of the present." The article gives evidence of very loose reading and thinking and very little acquaintance with the practice of Wesley's time, but is interesting because it states that the cow dung poultice is still used in England, as it is, or was a few years ago, in certain parts of the United States.

It is clear that we must not compare Wesley's therapeutics with those of his most eminent contemporaries. He did not pretend to special knowledge, but even when we compare his methods with those of physicians, we find a good deal to admire or to excuse. He treated symptoms only, but so did his contemporaries, and if he conceived diseases as foreign entities invading the body, so did most of the physicians of his century. He schematized medicine far too much, but so did many illustrious leaders of medicine. Brown was bad enough, but Röschlaub, one of Brown's most noted followers, Professor at Bamberg, Landshut and Munich, thought all therapeutics so far as recoverable diseases are concerned, could be learned in thirty axioms. The ordinary followers of Brown must have been shocking. So far as symptomatic diagnosis is concerned this has lasted to our own day, for even if we have gone beyond such names as "dropsy" or "fever," there is still a general tendency to be satisfied with the main diagnosis, whether of an infection, like typhoid fever, or pneumonia, or a process like diabetes or gout, and to carry out a schematic treatment, with little or no effort at learning either the peculiar variety of the main disease or the precise anatomic and functional condition of all the important organs.

As to treatment, in general Wesley's was much better than that of his contemporaries, in the sense that though often ridiculous it was rarely harmful. The others, true to their conception of disease as the result or the cause of vicious humors, of acrid blood, of baneful concoctions or fermentations, devastated their patients with violent drugs, bled them to extremitus, salivated them, kept open sores running for weeks or months. Wesley's consumptive, living on milk and breathing into a hole in the turf every day, was infinitely better off than Morton's, and so with many others.

If we cannot censure him for doing harm, can we explain away his failure to improve the practice of

3. Thomas, Burton G.: American Physician, November, 1906, p. 295.

his time as he evidently hoped to do? This, I think, is not difficult. If both the moderate and sober words of Sydenham and Cheyne, the violent invectives of Gideon Harvey and Dover had so little effect on the abuses of the period, it was unlikely that one who had so many other prejudices to overcome as Wesley had, could do better. Even at the end of the century the keen and merciless criticism of Hahnemann had but little influence on the crude and barbarous therapeutics of the period. The reason for failure in all cases I take to be the same. All of these would-be reformers, in varying degrees, were hampered by errors of their own; errors that must have been obvious to clear-thinking contemporaries in or out of the profession. All thought about disease in the same way, and all were obliged to do so until the discoveries in anatomy, physiology and chemistry opened a new way of thinking. After the beginning was made in the biologic conception of disease, systems could no longer expect much consideration, no matter how brilliantly they were exploited. And still we can see how many useless mixtures, how many unnecessary drugs, lumber the books and shelves. How many new preparations, no more promising than Wesley's simples, are daily used by the hopeful but credulous profession! And while Wesley's remedies were for the most part harmless nauseants, cathartics, aromatics or demulcents, the newer remedies are likely to be habit-forming, blood-destroying or anaphylaxis-producing, or in other ways distinctly harmful. Modern methods have even enlarged the field of practice once met by Wesley's little book with its simple guide. Wholesale drug houses have dozens of clerks who receive basketfuls of letters from physicians asking for help in trying cases. The diagnosis is no more accurate than in the case of Wesley's reader. The drug clerk advises the first remedy in his list, and if that does not bring results, the next, and so on. Among the laity the belief in medicines as exorcisers of disease seems almost as firmly fixed as ever. The strange or obscure, the alleged inventions of ignorant or savage people, appeal to them more strongly than the rational measures of the skilled and educated. The doctrines of Still have appealed to many more people than have the candid and reasonable recommendations of Weir Mitchell.

Still more interesting is Wesley's relation to superstitious or occult methods. Wesley was a child of his age in many ways. He was able to see the rational features in the practice of the best men of his time, like Sydenham, Cheyne, Floyer and Fothergill, but at the same time he was saturated with superstitions that go back to the earliest legends of medicine or that can be found among the most primitive races.

Thoroughly as he believed in some mystic forms of treatment, and firmly as he believed in the supernatural as he viewed it, he did not mix his medicine with religion, for his recommendation of prayer in treatment is very mild. It remained for the age of the greatest discoveries in natural science, and the period of the most rampant materialism and so-called rationalism, to develop the most varied and extreme methods of superstitious therapeutics, and to revive, without improvement, under the name of "New Thought," methods familiar thousands of years ago.

Preventogram.—Why pay for oxygen when you can get unlimited supplies by simply opening the windows?—*Buffalo Sanitary Bull.*

THE COMPARATIVE NUTRIENT VALUE OF COD LIVER OIL AND COD LIVER OIL CORDIALS

JOHN PHILLIPS STREET, M.S.
Chemist, Connecticut Agricultural Experiment Station.
NEW HAVEN, CONN.

For a long time cod liver oil has been recognized as an easily assimilable nutrient and reconstructive and of special value in wasting diseases. The unpalatability of the oil, however, has led to various devices to make it tasteless or to render it more acceptable to the stomach. Emulsions containing the oil in mixture with other substances were exploited, and doubtless served a useful purpose. The oil, however, but imperfectly concealed, was still disagreeable to many, and other preparations began to appear on the market, which claimed to retain the therapeutic virtues of cod liver oil without its disagreeable characteristics. This practice has been carried so far that now we find for sale cod liver oil preparations from which the oil has been removed in its entirety, and only the name remains. Certain of these products claim to "represent" the oil and to retain all its virtues; others are said to contain oil, while still others claim "all the valuable constituents" of the oil without the oil itself.

In the past, cod liver oil has been considered a food rather than a medicine, and its value attributed to the easily digestible and metabolizable oil it contains. This position, however, has been disputed. By some its therapeutic value has been attributed to the small amount of iodin present in the oil, but in recent years the suggestion has been made that its special potency depends on its peculiar fatty acids. In this connection the U. S. Dispensatory[1] says:

> Other oleaginous substances, certainly not less nutritious, have not been equally efficient, though taken in much larger quantities. If this be the true explanation, persons living chiefly on milk, which abounds in oil, or on fat pork, ought to show a special exemption from scrofulous complaints. The probability appears to us to be that, in consequence of some peculiar principle or principles it contains, it exercises a stimulant and alterative influence on the processes of assimilation and nutrition, thereby aiding in the production of healthy tissue.

Indeed, Osborne and Mendel[2] have shown in their experiments on albino rats that by substituting cod liver oil for a portion of the lard in their standard diets, growth was resumed after failure on foods containing commercial lard alone as the source of fat. Similar results were secured with butter-fat and egg yolk fat.

In the light of the theories advanced for the therapeutic value of cod liver oil, and the results secured by Osborne and Mendel with the oil itself, it seemed a profitable study to examine some of the prominent "oilless" preparations on the market to determine whether or not the claims made for them as nutrients were justified. Certain of the so-called cod liver oil preparations are termed "extracts" of cod liver oil, and are not made from the oil, but from the cod livers instead. As has been well said,[3] "They are preparations, which, if honestly made, might be worthy of trial, but they are improperly called 'extracts' of cod liver oil, since they do not contain the fat, which is the active constituent of the oil, but the extractives from the liver, which may or may not possess therapeutic virtues. So far as we know, however, no satisfactory evidence is forthcoming to indicate that such extractives have any therapeutic value."

---

[3] Fraud and Deception Connected with So-Called Cod Liver Oil Preparations, The Journal A. M. A., Oct. 13, 1906, p. 1207.

It was with preparations of this class that our experiments were made. Four of the more extensively advertised brands were selected, as they represent rather distinct types of this class of products, as the following claims of their labels will show:

Hagee's Cordial of the Extract of Cod Liver Oil, Compound.—"Tonic, stimulant, alterative, reconstructive, nutritive and digestive." "Each fluid ounce represents the extract obtainable from ⅓ fluid ounce of cod liver oil (the fatty portion being eliminated), 6 grs. calcium hypophosphite, 3 grs. sodium hypophosphite, ½ gr. salicylic acid (made from oil wintergreen), with glycerine and aromatics."

Vinol.—"The modern tonic reconstructor containing the medicinal extractives of fresh cod livers with peptonate of iron." "When the blood is poor, when more fresh blood is needed, when the weak need strength, when the throat and lungs are affected, TAKE VINOL."

Wampole's Perfected and Tasteless Preparation of an Extract of Cod Liver.—"Contains a solution of an extractive obtainable from fresh cod livers, the oily or fatty portion being afterward eliminated. This extractive is combined with liquid extract of malt, fluid extract of wild cherry and compound syrup of hypophosphites (containing calcium, sodium, potassium, iron, manganese, quinine and strychnine)."

Waterbury's Compound, Plain.—"Made from cod liver oil, digestive ferments, malt extract unfermented, hypophosphites comp. special, ext. cherry, eucalyptus, aromatics, etc."

Thus we have represented in our experiments an "extract" with hypophosphites, one with peptonate of iron, one with malt extract and hypophosphites and the alkaloids quinin and strychnin, and one with malt extract and hypophosphites without alkaloids.

In order to prepare a dry ration of suitable keeping properties, it was necessary to remove the alcohol and water from the various preparations. This was done by evaporation under reduced pressure at from 40 to 55 C. (104 to 131 F.). In the case of Hagee's Cordial it was claimed that one fluidounce of the preparation represented ⅓ fluidounce of cod liver oil, and in the subsequent substitution for cod liver oil in our rations, this ratio was used for all four products.

The composition of the four preparations was as shown in Table 1.

It is seen that these are very dissimilar preparations, the alcohol ranging from 7.50 to 18.69 per cent., the extract from 8.72 to 39.53 per cent. (10.81 of the 13.18 gm. of extract in Hagee's Cordial being glycerin), the ash from 0.305 to 1.967 per cent., the reducing sugars from 1.35 to 17.10 per cent., and the glycerin from a trace to 10.81 per cent. Wampole's contained quinin and strychnin, the others no alkaloids; salicylates were present in all but Wampole's; saccharin in Hagee's. The Pettenkoffer test for biliary acids gave a negative result in Hagee's and Wampole's; in Vinol and Waterbury's, small amounts of fatty acids were obtained, amounting to 0.016 and 0.032 gm. per hundred c.c., respectively, quite insignificant amounts.

The feeding experiments were made on albino rats of both sexes, which were placed, when about 6 weeks old, on a standard ration, No. 7, and after several months, when a failure to maintain weight was indicated,[4] an amount of dealcoholized cordial extract equivalent to 18 per cent. of cod liver oil was substituted for a portion of the lard, the cordial extract later being replaced by an equivalent amount of cod liver oil.

TABLE 1.—ANALYSES OF COD LIVER OIL PREPARATIONS

	Hagee	Vinol	Wampole's	Waterbury's
Specific gravity at 15.6 C.	1.0405	1.0111	1.1305	1.0499

THE RATIONS USED

The rations fed to the rats were as indicated in Table 2.

TABLE 2.—RATIONS FED THE RATS

RATION 7 (STANDARD)	Per cent.
Corn gluten	25 3
Milk albumin	11.0
Commercial protein-free milk	23.3
Corn-starch	10.7
Lard	29.7

RATION 8 (HAGEE'S)	Per cent.
Corn gluten	25.5
Milk albumin	11.0
Commercial protein-free milk	23.5
Corn-starch	10.5
Lard	17.7
Hagee's (extract)	11.8

RATION 10 (VINOL)	
Corn gluten	25.5
Milk albumin	11.0
Commercial protein-free milk	23.5
Corn-starch	10.5
Lard	23.9
Vinol (extract)	5.6

RATION 11 (WATERBURY)	
Corn gluten	25.5
Milk albumin	11.0
Commercial protein-free milk	23.5
Corn-starch	10.5
Lard	17.6
Waterbury (extract)	11.9

RATION 12 (WAMPOLE'S)	
Corn gluten	25.5
Milk albumin	11.0
Commercial protein-free milk	23.5
Corn-starch	10.5
Lard	4.1
Wampole (extract)	25.4

RATION 13 (COD LIVER OIL)	
Corn gluten	25.5
Milk albumin	11.0
Commercial protein-free milk	23.5
Corn-starch	14.0
Lard	8.0
Cod liver oil	18.0

The corn gluten contained 7.69 water, 0.14 ash, 6.63 nitrogen, 4.24 nitrogen soluble in hot alcohol (= zein 28.85), 12.63 other proteins by difference,

---

[4] Osborne and Mendel have shown (Jour. Biol. Chem., 1913, xv, 311) that mixtures of purified protein, lard, starch and protein-free milk have been singularly efficient for a time in promoting growth of young rats. In from sixty to 100 days or more, however, normal growth stops; the animals may remain at constant weight for a few days, or grow very slowly, and then suddenly decline and die unless a change is made in the diet. The substitution of butter-fat, egg yolk fat, or cod liver oil for a portion of the lard in the ration, in the experiments of these authorities, brought prompt recovery and continuation of normal growth.

41.48 total protein and 4.83 per cent. fat. The milk albumin contained 4.69 water, 22.01 ash, 8.85 nitrogen (= 56.46 protein), 1.03 fat and 18.81 per cent. lactose. The commercial protein-free milk was crude milk-sugar. Before use in the rations, the corn gluten was thoroughly extracted with ether to remove the fat.

In all, nineteen rats were used, five each with Vinol and Wampole's, six with Hagee's, and three with Waterbury's. Rats 19 and 27 on Hagee's, Rat 31 on Vinol and Rat 32 on Wampole's showed certain abnormalities during the experiment, and are excluded from the present discussion.

The rats at first were weighed weekly, but later twice a week, or oftener, when a marked change in weight seemed imminent. It is unnecessary to give the detailed weights of the rats when on the standard ration, especially as in some cases they were kept on this ration for over four months. Only enough of the weighings on the standard ration will be given to show the steady increase in weight of the rats, until the approach of a change in the ration, when the semiweekly weighings will be shown. In general no change in the ration was made until two successive weighings showed a distinct loss of weight. There were certain exceptions to this rule which will be noted in the proper place.

HAGEE'S CORDIAL

The results secured with Hagee's Cordial are given in Table 3.

TABLE 3.—RATION 7 (STANDARD), RATION 8 (HAGEE), RATION 13 (COD LIVER OIL)*

212	169	163.9
219	170	168.2

* In the tables, ♂ denotes male, and ♀ female.

None of the four rats did well on Hagee's Cordial; in fact, they lost from 1.2 to 15.4 gm. during feeding periods of from seven to fourteen days. With Rat 33 there was a slight temporary gain of 1 gm. during one week, where normally the gain should have been 6 gm., but even this small gain was overcome during the next week by a loss of 2.2 gm. The rats failed so quickly when put on Hagee's Cordial that in two cases the animals did not recover even when put on the full cod liver oil ration. Our experience with these two rats prompted us not to allow the other rats to remain too long on the Hagee ration, and the shift in diet was made somewhat sooner than would normally have been the case; in fact, with Rat 33 a slight gain in weight was evidenced just before the shift was made.

The following tabulation summarizes the results obtained by feeding the Hagee ration:

Rat 28	in 7 days	lost 15.4 gm.,	or	8.5 per cent.	of its weight
Rat 29	in 7 days	lost 12.4 gm.,	or	12.0 per cent.	of its weight
Rat 33	in 14 days	lost 1.2 gm.,	or	0.9 per cent.	of its weight
Rat 34	in 7 days	lost 7.2 gm.,	or	4.5 per cent.	of its weight

The gains made when cod liver oil was substituted for Hagee's Cordial were as follows:

Rat 28	in 53 days	gained 41.4 gm.,	or	25.1 per cent.	of its weight
Rat 29	in 49 days	gained 74.3 gm.,	or	81.6 per cent.	of its weight
Rat 33	in 35 days	gained 27.1 gm.,	or	20.8 per cent.	of its weight
Rat 34	in 60 days	gained 13.6 gm.,	or	8.8 per cent.	of its weight

Inasmuch as the feeding periods were of different duration, the effect of the two rations is better shown by a comparison of the normal gain the animals should have made during the feeding periods with that actually obtained. This is shown in Table 4.

TABLE 4.—COMPARISON OF NORMAL GAIN WITH ACTUAL GAIN ON HAGEE RATION AND COD LIVER OIL

Rat	Hagee Ration		Cod Liver Oil Ration	
	Normal Gain, Gm.	Actual Gain, Gm.	Normal Gain, Gm.	Actual Gain, Gm.
28 ♂	5	—15.4	49	41.4
29 ♂	7	—12.4	35	74.3
33 ♀	10	— 1.2	12	27.1
34 ♀	2	— 7.2	18	13.6

In other words, the four rats during the *Hagee* period, instead of gaining the normal 24 gm., actually lost 36.2 gm., while during the cod liver oil period instead of gaining 114 gm., they gained 156.4 gm.

The inferiority of Hagee's Cordial as a reconstructive and a nutrient compared with ordinary cod liver oil is apparent.

VINOL

The results secured with Vinol are given in Table 5.

170	218	188.8
173	220	189.8
177	223	198.8
180	226	200.5

The four rats fed the Vinol ration gave somewhat more favorable results than those fed Hagee's Cordial, two showing slight gains in weight. Rat 21, however, was apparently weakened by Vinol, as it required thirty-five days of feeding the cod liver oil ration to bring it back to the weight shown prior to the Vinol feeding.

The following tabulation summarizes the results obtained by feeding the Vinol ration:

Rat 17 in 17 days gained 5.1 gm., or 3.8 per cent. of its weight
Rat 18 in 22 days gained 6.0 gm., or 4.0 per cent. of its weight
Rat 21 in 35 days lost 8.0 gm., or 5.8 per cent. of its weight
Rat 30 in 11 days lost 5.9 gm., or 3.5 per cent. of its weight

The gains made when cod liver oil was substituted for Vinol were as follows:

Rat 17 in 25 days gained 27.0 gm., or 19.9 per cent. of its weight
Rat 18 in 20 days gained 17.9 gm., or 11.4 per cent. of its weight
Rat 21 in 39 days gained 6.7 gm., or 5.2 per cent. of its weight
Rat 30 in 17 days gained 35.9 gm., or 21.8 per cent. of its weight

The feeding periods during which Vinol and cod liver oil were supplied to the rats were more nearly equal than with the Hagee ration, and a direct comparison is possible. However, Table 6 shows a comparison between the normal and actual gains of the animals for the different feeding periods.

TABLE 6.—COMPARISON OF NORMAL GAIN WITH ACTUAL GAIN ON VINOL RATION AND COD LIVER OIL

Rat	Vinol Ration		Cod Liver Oil Ration	
	Normal Gain, Gm.	Actual Gain, Gm.	Normal Gain, Gm.	Actual Gain, Gm.

Cod Liver Oil Ration		
201	168	190.5
208	169	190.7
215	170	192.5

In other words, the four rats instead of gaining the normal 42 gm. during the Vinol period, actually showed a net loss of 1.5 gm., while during the cod liver oil period instead of gaining 42 gm., they gained 87.5 gm.

The foregoing results show the superiority of ordinary cod liver oil over Vinol, "the modern tonic reconstructor," and that "when more flesh is needed, when the weak need strength," these results are much more effectively secured with the oil itself.

WAMPOLE'S PREPARATION

The results secured with Wampole's Preparation are given in Table 7.

All of the four rats fed the Wampole Preparation showed gains in weight although in two cases the gains were quite insignificant. Rat 36 showed substantial gains during the period, but during the last eleven days suddenly lost 30.9 gm., and was then shifted to the cod liver oil ration, when in three days it recovered 15.9 gm. of this loss. Rat 37 was shifted to the cod liver oil ration before two distinct failures to gain had been shown under the Wampole ration, but in the first week under cod liver oil it gained 16.5 gm., more than it had gained in eighteen days with the Wampole ration. The Wampole Preparation showed a much greater ability to sustain or gain weight than either Hagee's or Vinol.

The following tabulation summarizes the results obtained by feeding the Wampole ration:

Rat 26 in 18 days gained 3.0 gm., or 1.9 per cent. of its weight
Rat 35 in 39 days gained 13.7 gm., or 6.5 per cent. of its weight
Rat 36 in 39 days gained 0.5 gm., or 0.3 per cent. of its weight
Rat 37 in 39 days gained 34.2 gm., or 24.5 per cent. of its weight

The gains made when cod liver oil was substituted for the Wampole Preparation were as follows:

Rat 26 in 27 days gained 33.8 gm., or 21.1 per cent. of its weight
Rat 35 in 17 days gained 6.1 gm., or 2.7 per cent. of its weight
Rat 36 in 35 days gained 23.1 gm., or 11.7 per cent. of its weight
Rat 37 in 21 days gained 18.5 gm., or 10.6 per cent. of its weight

The feeding periods during which the Wampole Preparation was given were considerably longer than those during which cod liver oil was fed. Table 8 shows a comparison between the normal and actual gains of the animals for the different feeding periods.

TABLE 8.—COMPARISON OF NORMAL GAIN WITH ACTUAL GAIN ON WAMPOLE RATION AND COD LIVER OIL

Rat	Wampole Ration		Cod Liver Oil Ration	
	Normal Gain, Gm.	Actual Gain, Gm.	Normal Gain, Gm.	Actual Gain, Gm.
26 ♀	11	3.0	10	33.8
35 ♂	33	13.7	15	6.1
36 ♂	24	0.5	33	23.1
37 ♀	15	34.2	4	18.5

In other words, the four rats on the Wampole ration gained 51.4 gm. instead of the normal 83 gm., while during the cod liver oil period they gained 81.5 gm. instead of the normal 62 gm.

It would appear that the malt extract or the sugar present in Wampole's Preparation had increased its nutritive value over Hagee's Cordial and Vinol, *but even with this addition it fell far behind ordinary cod liver oil as a source of nutriment.*

WATERBURY'S COMPOUND

The results secured with Waterbury's Compound are given in Table 9.

Two of the rats when fed the Waterbury ration showed slight gains in weight, but the third lost 13.4 gm. in two weeks. With none of these rats was a marked failure secured on the standard ration at the time of the shift to the Waterbury ration. They had rather ceased to grow instead of showing a distinct loss in weight. Rat 22 had gained but 2.6 gm. in seven days, Rats 23 only 2.2 gm. in eight days, and Rat 25 only 0.6 gm. in ten days, whereas they should have gained 4 gm. in each case. Likewise no very distinct failure on the Waterbury ration had been shown when the rats were changed to cod liver oil, although the good effect of the change was noticeable at once in gains of 7.8, 10.3 and 28.1 gm., respectively, in one week. In other words, the rats in one week gained on cod liver oil much more than they did in the full feeding periods of from fourteen to thirty days on the Waterbury ration.

170	158	158.9
174	159	171.7
177	160	174.4
181	161	175.8

The following tabulation summarizes the results obtained by feeding the Waterbury ration:

Rat 22 in 30 days gained 4.6 gm., or 3.2 per cent. of its weight
Rat 23 in 30 days gained 9.1 gm., or 6.7 per cent. of its weight
Rat 25 in 14 days lost 13.4 gm., or 9.3 per cent. of its weight

The gains when cod liver oil was substituted for the Waterbury Compound were as follows:

Rat 22 in 60 days gained 15.6 gm., or 10.5 per cent. of its weight
Rat 23 in 56 days gained 26.8 gm., or 18.4 per cent. of its weight
Rat 25 in 18 days gained 45.0 gm., or 34.4 per cent. of its weight

Table 10 shows a comparison between the normal and actual gains of the animals for the different feeding periods.

TABLE 10.—COMPARISON OF NORMAL GAIN WITH ACTUAL GAIN ON WATERBURY RATION AND COD LIVER OIL

Rat	Waterbury Ration		Cod Liver Oil Ration	
	Normal Gain, Gm.	Actual Gain, Gm.	Normal Gain, Gm.	Actual Gain, Gm.
22 ♀	14	4.6	17	15.6
23 ♀	14	9.1	17	26.8
25 ♀	4	−13.4	8	45.0

In other words, the three rats on the Waterbury ration showed a net gain of 0.3 gm. instead of the normal 32 gm., while during the cod liver oil period they gained 87.4 gm. instead of the normal 42 gm.

Even the presence of malt extract failed to increase appreciably the nutritive value of the Waterbury Compound, cod liver oil again showing a very marked superiority as a source of nutriment.

SUMMARY

Table 11 gives a summary of the actual gains of the fifteen rats on the four rations, compared with the gains shown by cod liver oil and those shown by normal rats at the same period of their life history.

TABLE 11.—SUMMARY OF RESULTS*

Rations	Total Normal Gain, Gm.	Total Actual Gain, Gm.	Average Normal Gain, Gm.	Average Actual Gain, Gm.
Hagee ration	24	−36.2	6	−9.1
Cod liver oil ration	114	156.4	28.5	39.1
Vinol ration	42	−1.5	10.5	−0.4
Cod liver oil ration	42	87.5	10.5	21.9
Wampole ration	83	51.4	20.8	12.9
Cod liver oil ration	62	81.5	15.5	20.4
Waterbury ration	32	0.3	10.7	0.1
Cod liver oil ration	42	87.4	14	29.1

* In this table are given the totals and averages of the figures already presented in Tables 4, 6, 8 and 10.

In considering the effect of these preparations as general medicines, their alcohol content must not be overlooked. Hagee's Cordial contains 7.50 per cent. of alcohol by volume, Vinol 18.60 per cent., Wampole's Preparation 16.59 per cent., and Waterbury's Compound 11.25 per cent. Full strength whisky contains 50 per cent. of alcohol by volume. By following the doses prescribed by the manufacturers of these preparations, the user would consume daily the following equivalents of full strength whisky:

In Hagee's Cordial..........	0.24 fluidounce
In Vinol....................	0.8 fluidounce
In Wampole's Preparation...	0.7 fluidounce
In Waterbury's Compound...	0.6 fluidounce

These amounts of alcohol are by no means negligible and doubtless explain to a considerable extent the source of the alleged tonic virtues of these preparations.

The results of the experiments may be summarized as follows:

Hagee's Cordial failed to sustain rats during periods of seven and fourteen days, the rats showing a loss in weight of 36.2 gm., instead of the normal gain of 24 gm.

Vinol in two cases sustained and in two cases failed to sustain growth during periods of from eleven to thirty-five days, the net loss in weight of the four rats being 1.5 gm., instead of the normal gain of 42 gm.

Wampole's Preparation in three cases sustained and in one case promoted growth in rats during periods of eighteen and thirty-nine days, showing, however, only 51.4 gm. gain in weight instead of the normal 83 gm.

Waterbury's Compound in two cases sustained and in one case failed to sustain rats during periods of fourteen and thirty days, the net gain in weight, however, being but 0.3 gm. instead of the normal 32 gm.

Cod liver oil showed a gain of 42.4 gm. over the normal, while with the same rats Hagee's Cordial showed a loss of 60.2 gm. Cod liver oil showed a gain of 45.5 gm. over the normal, while with the same rats Vinol showed a net loss of 43.5 gm. Cod liver oil showed a gain of 19.5 gm. over the normal, while with the same rats Wampole's Preparation showed a loss of 31.6 gm. Cod liver oil showed a gain of 45.4 gm. over the normal, while with the same rats Waterbury's Compound showed a net loss of 31.7 gm.

Not only did cod liver oil show a marked superiority as a source of nutriment over Hagee's Cordial, Vinol, Wampole's Preparation and Waterbury's Compound, but it also showed a remarkable reconstructive and recuperative power in its ability to enable rats to gain weight rapidly and steadily after having suffered from a deficiency in nutriment when fed the four preparations named above.

I wish to express my appreciation of the courtesies extended to me by my colleagues, Dr. T. B. Osborne, Prof. L. B. Mendel, Dr. A. J. Wakeman and Miss Edna L. Ferry in conducting these experiments. To Mr. Hugo Lange my thanks are also due for his efficient assistance in the care, feeding and weighing of the animals.

SYMPTOMS AND SIGNS OF GASTRIC CANCER: AN ANALYSIS OF 712 CONSECUTIVE OPERATIVELY AND PATHOLOGICALLY PROVED CASES *

FRANK SMITHIES, M.D.
Gastro-Enterologist to Augustana Hospital
CHICAGO

The material forming the basis of this report was obtained from my records of cases at the Mayo Clinic and my service at Augustana Hospital, Chicago. Of the 712 cases studied, all had been operatively and pathologically proved to be gastric cancer. Doubtful cases were excluded.

Sex.—The sex ratio was approximately that of gastric ulcer; namely, 483 males and 229 females, or 2.1 to 1.

Age.—While instances were recorded at as low as 20 years, the age of more than three-fourths of the patients ranged between the fifth and the eighth decades.

Etiologic Factors.—A family or blood-relationship history was proved in 9.4 per cent. of cases. A history of trauma was demonstrated in 3.1 per cent. of instances. In 2.2 per cent. the trauma appeared to precipitate symptoms.

With respect to *definite symptomatology*, it is well to admit here that 1.9 per cent. of cases gave absolutely no symptoms pointing to our clinical conception of gastric cancer. In such instances, exploratory operation or post-mortem examination gave the diagnosis.

Another appropriate admission is that we have no proved clinical procedure, other than history taking, which enables us to make early diagnosis of gastric cancer. Our so-called "early diagnoses" are usually lucky guesses, or are incidents in gastric exploration. The only dependable early diagnosis is made after laparotomy by a capable surgical pathologist by means of sections of tissue stained and examined under high power.

Information obtained by means of the Roentgen ray, by the estimation of the formol index, by the Wolff-Junghans' test or by the edestin digestion test, sometimes is of aid in *excluding cancer* in its early stage, but is of relatively little value in determining for us the presence of the earliest type of cancer—the cancer which we can honestly say is surgically curable.

It is to be more generally realized as men make tabulations of cases and then study them with liberal minds, that in proved cancer cases we have clinically at least three types of happenings leading up to a diagnosis of cancer. My study indicates that the following is the order of their relative incidence: 1. A symptom-complex of two very *definite* and *different* stages: (a) gastric disturbance, non-malignant and generally chronic; (b) gastric malfunction of malignant type. 2. A symptom-complex generally of a distinctly apparent, pernicious nature. 3. A group of cases in which there is usually evidence of years of gastric disturbance of irregular form, clinically, on which is superimposed a type of affection easily recognized as malignant.

Group 1.—Symptom-Complex Wherein Two Definite and Different Stages of Disease are Present.—This group furnishes 61 per cent. (434 cases) of my series. The average duration of all symptoms in the first stage was 11.7 years. The average duration of all symptoms in the second period is nearly 6 months. The two periods differ markedly. The anamnesis brings out very well the characteristic manifestations of each period. It is only by disengaging the patient from his present state and endeavoring definitely to locate his first departure from gastric health that one gets the key to the situation.

(a) In 61 per cent. of my proved cancer cases the total time of gastric complaint was somewhat over 12 years. For practically 11½ years the symptomatology was that which, clinically, we associate with chronic gastric ulcer. This first period was characterized by a long series of *attacks* of *"indigestion."* These attacks were associated with *epigastric distress or pain* in 88 per cent. of instances. In 85 per cent. the distress had some relation to the taking of food, the interval being longer or shorter according to the character of food taken. After a solid, mixed meal, the pain relief was longer, but when it recurred it was unmistakably more severe than when lighter forms of nourishment had been indulged in. Other forms of pain relief were alkalies, vomiting and diet. In 54 per cent. of instances the pain was referred to some part of the back. The appetite was usually limited by the fear of taking food and thus causing pain, or by the dread of bringing on bleeding. The food desire in this first stage was generally strong. Weight was lost in the attacks but gained between them. The average *weight loss* at this period was 17.4 pounds. *Constipation* was noted in 52 per cent. of instances. In 8 per cent. there was *diarrhea*. *Vomiting* occurred in 60 per cent. Rather more than 70 per cent. vomited in attacks. The time of vomiting was generally when distress was most marked. *Bleeding* (hematemesis or melena) was noted in 17 per cent. of instances during this stage. Of the whole number bleeding, 49 per cent. had bled at least two years prior to coming under observation. Of those who bled within the two year period over 65 per cent. were of the group with long previous history. In this group *anemia* was rarely marked, the average hemoglobin being toward 80 per cent. (Tallquist or Dare).

(b) If this class of cases pursues the above outlined history, the following may ensue: (1) Complete healing with stoppage of all symptoms; (2) typical chronic, *benign* gastric ulcer may result, or (3) gastric cancer may form, whereas previously there had been but a simple process. And no one can prognose in a given case presenting the clinical picture of gastric ulcer just *which kind of ulcer will heal or continue its benign course or which will ultimately form the suitable ground for cancer.* When we recall the pathology in these cases we can hardly blame ourselves for not catching the ulcer clinically in transition to cancer. All ulcers have about and in them hyperplastic tissue—tissue of defense and of healing. No one can tell in a given case when this hyperplasia will change over from the simple type to the malignant form. *Clinically* we are only warned by the appearance in a patient of a more or less continuous gastric disorder, where attacks had before been the rule. This may occur with or without the onset of pyloric obstruction. Where previously there was trouble in spells, with food relief, we note food aggravation, night distress, delayed vomiting, continuous presence of occult blood in the stools, anemia, cachexia, weight loss steadily maintained, weakness, and that peculiar, hopeless apathy exhibited by the fascias. Pain is rarely marked. Vague distress, "heavy feeling" or soreness in the epigastrium are the rule. Severe pain was observed in but 19 per cent. of our cases. It was of "colicky" nature in 14.2 per cent. Gassy and bloated sensations are generally constant and annoying.

---

* Read at the Annual Session of the American Gastro-Enterological Association, Atlantic City, N. J., June 20, 1914.

In the second stage vomiting becomes more constant and is frequently in greater amount. The odor of the vomitus changes from distinctly sour or yeasty to cheesy or rancid. The color of the vomitus may exhibit little if any alteration. Inasmuch as more than 96 per cent. of my cases of gastric cancer were of the medullary type, oozing of blood was not uncommon. This pathologic state usually imparts a tan to deep brown color to vomitus or stomach extracts. In a little more than 17 per cent. of my 712 cases of gastric cancer was the vomitus of the classic "coffee ground" color. When it presented these characteristics the disease was far advanced in 84.2 per cent. of instances, and inoperable (so far as resection was concerned) in 77 per cent. The vomitus generally shows excess of thick, tenacious mucus, intermixed with sizable food remnants, frequently poorly chymified.

The stools rarely show macroscopic changes unless hemorrhage complicates, or liver, pancreas or adjacent hollow viscera become involved. On a milk diet, chemical tests for blood were positive in 83.4 per cent. of cases tested.

Group 2.—Symptom-Complex in Cases Clinically Malignant from the Inception of Gastric Malfunction.—Of the 712 cases of gastric cancer studied, 31.6 per cent. (225 cases) fell in this group. Careful history taking failed to elicit any clinical type of gastric complaint in these patients previous to an average time of 7.4 months before they came under observation. It should be emphasized that because no gastric disturbance had been previously noted, the conclusion should not be forced that such patients had had no gastric pathology previously. On the contrary, our postmortem or laparotomy findings of healed ulcers, and even of gastric new growths in individuals who had had no clinical pointings referable to gastric disease, should lead us to exercise caution in insisting when or how malignant processes in the stomach arise. The longest history of gastric symptoms in this group extended over nearly three and one-fourth years; the shortest barely three weeks.

In this group, which I have, from the pathologic view of the disease, styled "primary" gastric cancer, often it is extremely difficult to state from clinical presentings just when cancer began. Many so-called "primary" cancers have histories extending over weeks of time, where the symptom-complex closely approximates that which our present-day vogue associates with gastric ulcer of the continuously active and progressive form. The clinical picture is different, however, in one important respect. To the symptom-complex is added the manifestations of a malignant systemic poisoning. Instead of fairly definite "attacks" of ulcer type of dyspepsia, and that alone, the process is continuous and associated with progressive weakness, anemia, weight loss with cachexia, vomiting, changing rapidly to the rancid kind. Epigastric pain may be severe and prostrating at first, but later moderates in severity, is not relieved, but is aggravated, by food. It ultimately becomes continuous. I have frequently had strikingly impressed on me the "ulcer-features" clinically in primary gastric cancer. The hurried progression to definite malignancy has seemed to emphasize the necessity for separate recognition clinically of the term "chronicity" in its pathologic sense and in its time-factor sense, meaning weeks, months or years of duration of disease. In many of these primary gastric cancers the clinical gamut of "gastritis," "ulcer" and "cancer" may be run in a few months or even weeks. The whole course of the ailment is compressed into a sort of "tabloid," with regard to time, from which parts are readily segregated that closely approximate clinically those stretched over years exhibited by the great group of cancers forming my Group 1. With this state of affairs it is not to be wondered at that patients present themselves to the specialist or the surgeon only when tumor appears in the epigastrium or when hopeless cachexia warns of impending death.

While the above type of onset of primary gastric cancer is not infrequent, fully two-thirds of this group have more or less vague recollections of how they were affected gastrically before loss of appetite, weakness, mental inertia, abdominal distress, weight loss or epigastric "hardness," "knob" or "lump" warned them that something graver than "chronic indigestion" impended. Rarely is the transition from perfect gastric health to the present state a rapid one. Aversion to certain forms of food (as meat, milk, sweets or legumes) is an early manifestation. While the appetite for some viands may be keen, the aversion to others may be marked and, for the individual, radical. Eructations, often of extremely disagreeable taste, generally become pronounced early. Gassy distention is troublesome. Unexplained nausea, with or without general weakness, manifests itself. In 17 per cent. of my cases of this group diarrheic stools appeared without apparent cause. Vomiting may be the first symptom and its copiousness pronounced and alarming. It is generally bitter, sour, cheesy, or may be "rotten" in taste. Vomiting was observed in 79 per cent. of this class. In 64 per cent. of those vomiting it was a daily occurrence. In more than 80 per cent. "delayed" vomiting was exhibited.

Consideration of the types of cases making up my grouping of "primary" gastric cancer would be incomplete without mention of that class which I have styled "fulminant" cancer. In my series, there were thirteen instances (5.7 per cent.) in which the whole history of the affection up to the time of laparotomy covered less than seven weeks. The average age of these patients was 49 years.

In this class, profound cancer intoxication was marked from the time of the first departure from gastric health. In nine instances, fever rose as high as 102 F. The leukocytes averaged 14,800. Anemia was of lower grade than is usual in gastric cancer. The hemoglobin averaged 62 per cent. Weakness, weight loss, mental dulness, foul eructations and copious vomiting, gassy distention of the abdomen, epigastric soreness and the appearance of a rapidly enlarging supranavel mass occurred with astonishing speed. At operation the malignant process was always inoperable and perigastric lymphatic gland invasion extensive. The pathologic examinations of tissue removed showed cancer of the medullary type. The very rapid progression in this class of cases is not explained on the basis of the character of the tumor. I have shown that more than 96 per cent. of the cancers in my series were encephaloid, and yet rapid extension, such as I have outlined in this "fulminant" class, is not generally seen. The explanation for this in the varying resistance of the tissues of the individual patient, is not wholly satisfactory.

Group 3.—Gastric Malignancy Following Long History of Clinically Atypical Dyspepsia or Dyspepsia of Extragastric Origin.—This division comprises thirty-nine cases (5.5 per cent.). Two markedly different types of gastric malfunction are brought out by careful history taking. The clinical manifestations preceding those evidently malignant, extended over an average period of 9.4 years. The time covered by the supervening malignant stage averaged 5.9 months.

The clinical symptomatology of the affections when they were apparently of benign nature usually pointed to disease of the gall-bladder, appendix, large bowel or the pancreas. Seven patients of this class had had previous operations performed for anomaly of the appendix or gall-bladder or both. In four instances, gall-stones were found when laparotomy was made for the gastric cancer.

The clinical symptomatology when the malignant period supervened was in every way similar to that of the second period of cases making up Group 1 or of some portion of that exhibited by those in Group 2. The point to be emphasized is that after years of gastric departure from health, of atypic form, but evidently benign, so far as our clinical knowledge extends, the picture changed apparently abruptly to that of definite malignancy. It is only in those patients who had recently submitted to laparotomy for extragastric disease, however, that we can positively state that gastric ulcer or gastric cancer with atypic clinical manifestations had not existed for some time previously.

CONCLUSIONS

There is at present no known medical cure for gastric cancer. We have, as yet, no dependable means at our command for the recognition of the disease at a stage when we can positively state that the affection is surgically curable.

The cases of gastric cancer early diagnosed are those in which the clinical symptomatology is that which we associate with chronic gastric ulcer, and in which laparotomy has been urged on the suspicion that cancer might be present.

Where microscopists disagree regarding the diagnosis of sections of extirpated tissue, clinicians can scarcely be expected to make early diagnosis of gastric cancer before laparotomy.

The question for clinicians and pathologists to settle is not how many cancers had previous ulcer pointings, nor how frequently gastric ulcer changes from simple to malignant form, but just how one is to tell, clinically, in a given case of chronic gastric ulcer, what future course it is destined to pursue. This is the crux of the situation. At present we have no means of prognosing the future course of any gastric ulcer, acute or chronic. The life history of the affection seems to depend on certain unknown factors that are apparently highly individual.

122 South Michigan Boulevard.

TORTICOLLIS *

HENRY J. FITZ SIMMONS, M.D.
BOSTON

The following paper is a critical analysis of one hundred cases of distortion of the neck which were entered in the records of the Boston Children's Hospital as torticollis. This analysis has been made in comparison with the findings as reported in the literature of the subject. The cases have been taken from the records of the Children's Hospital in the order in which they applied for treatment.

Any deforming relation between the head and the neck in which the sternocleidomastoid muscle was chiefly involved has been considered as torticollis, whether of congenital or acquired origin.

The sternomastoid muscle has its origin from the sternal notch and the sternal end of the clavicle and is inserted into the mastoid process of the temporal bone. The sternal and the middle portion of the muscle receives its blood supply from the sternomastoid branch of the superior thyroid artery. Unilateral contraction of this muscle pulls the head toward the shoulder, but elevates the chin and turns it away from the side of the contracting muscle. The other muscles about the neck which are most frequently involved in conjunction with the sternomastoid muscle are the scalenus anticus, the trapezius and the splenius capitis. The trapezius causes a more backward inclination and rotation of the head. The splenius capitis bends the head backward and toward the contracting muscle, but does not turn the chin in the opposite direction. The nerve supply to the sternocleidomastoid muscle is from the spinal accessory. The external portion of this nerve leaves the skull by the jugular foramen and descends obliquely outward to the sternocleidomastoid muscle and disappears under the muscle at a distance of about 2 inches from the apex of the mastoid process.

The pathologic work done on torticollis has not been extensive. The most interesting and most valuable has given rise to certain theories, advanced to explain the causation of congenital torticollis.

Lüning and Schulthess[1] have published the details of an autopsy on a child 5 months old, delivered by forceps, who showed at the time of birth a swelling of the middle part of the sternomastoid muscle and this muscle was two-thirds of an inch shorter than the corresponding muscle. Haüsinger[2] reports a case in which one sternomastoid muscle was 9 cm. long and the other was only 6.5 cm. long. The pathologic study in the case of a child 14 days old in which a swelling the size of a hazelnut developed two days after birth showed microscopically a chronic interstitial myositis with no trace of blood pigment. This condition must have originated in intra-uterine life and a true hematoma could not have existed. A peculiar degeneration of muscle fiber is described by Volcker[3] as being seen after prolonged partial obstruction to the circulation to the muscle. The changes were seen in the microscopic study of some sternocleidomastoid muscle excised in cases of congenital torticollis. Nové-Josserand and Vianny[4] from careful study of the blood supply under consideration showed it to be of such a character that it could be easily interfered with. The middle and sternal portions of the muscle, as has been said before, are supplied by the sternomastoid branch of the superior thyroid artery. When this is ligatured, injection material thrown into the common carotid or subclavian vessels fails to appear in the areas of distribution of the arteries in question, showing that it has little or no anastomosis with its neighbor. Further, the circulation in this small muscular vessel is readily obstructed in certain positions of the head. Thus experimentally, in the bodies of twenty newly born infants it was shown that later flexion of the head, with elongation of the neck and particularly partial flexion with torsion of the neck, prevented any injection reaching the muscle. The injection material was arrested at the anterior border of the muscle, the lumen of the artery being obliterated at that point. Volcker believes that the hematomas reported were probably postobstructive edema. Anomalies in the position and size of the arteries may explain the cause of some cases of congenital torticollis. The pathologic study made of excised portions of contracted muscles has shown the waxy degeneration of Zenker, which has been described as a "sclerotic interstitial myositis culminating in a more or less hardening of the muscles, with a subsequent shortening."

Etiology.—The etiology of acquired torticollis is varied, but is usually obtainable. It is secondary to some injury or disease of the structures of the neck. The simple form due to mechanical reasons, as scar contraction and trauma, is not uncommon. This form may almost be called chronic; and in this group there is a type of case which is apparently more common than is supposed. By this is meant that chronic form of torticollis due to a traumatism of the head or neck, which may be called "unilateral displacement of one of the cervical vertebrae." In the group of cases analyzed three were found which are believed to be of this type. Cases of distortion due to cellulitis of cervical glands, are, as a rule, transitory and not difficult to diagnose or treat with satisfactory result. This may be said of the distortion following tonsillitis, pharyngitis, measles, toothache, earache, etc. It is believed by some that this painful type of torticollis is due to an irritation of the peripheral nerve which results in active contraction of the neighboring muscles, but this belief has not been universally accepted, as it lacks pathologic confirmation. The irregular types of torticollis due to paralysis, ocular or physical defects, as well as spasmodic torticollis, have not been considered in this analysis, as they were not observed in any of the cases studied. The theories advanced as to the causation of congenital torticollis are still only theories. The most acceptable will be mentioned.

Stromeyer[5] believes that congenital torticollis is usually due to the rupture of the sternocleidomastoid muscle and to a subsequent myositis about the hematoma, which may involve and ultimately destroy a large part of the substance of the muscle, replacing it with fibrous tissue which, as it contracts, causes the deformity. Stromeyer's views have not been accepted by those who have studied operative material from cases of torticollis. His views do not explain the presence of torticollis in extra-uterine pregnancy, as described by Joachimstal[6] and Volcker,[3] and in those cases studied immediately after birth in which the characteristic structural changes have been seen. It is also obvious that time is required for the development of such changes in the muscle and structures of the neck, as has been observed in cases of torticollis, to believe that the condition is other than that dating from intra-uterine life. The history of swelling of the sternomastoid muscle is obtained no more often than it is not obtained.

Of forty cases reported by Maass,[7] twenty-three gave a history of pelvic presentation. In the series studied, 7 per cent. of the congenital cases analyzed gave a history of instrumental delivery. Tumor of the sternomastoid muscle does not necessarily mean a torticollis. Whitman[8] reported seven cases in which there was a swelling of the sternomastoid muscle and no torticollis subsequently developed. Keetley[9] was able to find only eleven cases of torticollis developing from thirty cases of hematoma of the sternomastoid muscle. I was able to find a history of tumor in five cases of proved acquired torticollis, and in ten cases of congenital tumor of the sternomastoid muscle in which there was a congenital torticollis. It may be seen that this theory advanced by Stromeyer is improbable for the following reasons: 1. Rupture of muscle in other parts of the body is never followed by myositis and contracture. 2. It has been demonstrated by Heller[10] that it is impossible to cause myositis and contracture in animals unless infected by actual pyogenic organisms. 3. Most of the cases seen after birth present no evidence of hematoma or injury. 4. Cases of hematoma of the sternomastoid muscle are, as a rule, not followed by torticollis.

The theory held by some writers that congenital torticollis is caused by a constrained or fixed position in the uterus for a longer or shorter time before birth, needs only be mentioned.

The mechanical theory of intra-uterine malposition, fixations of the head and neck by amniotic adhesions and the effect of obliquity of the fetal head, fails to explain why a special lesion of the sternomastoid muscle is present and why the neighboring parts are not involved as well. The simple traumatic theory does not satisfactorily explain those cases of extra-uterine pregnancies in which torticollis has been demonstrated. It would seem likely that injury to the sternomastoid during birth is more apt to take place if there has been an intra-uterine shortening of the muscle. Mikulicz[11] explains the injury which happens

to the sternomastoid muscle as being caused by compression of the umbilical cord, inducing forced respiratory movements while the fetal head is still engaged in the maternal passages. The sternomastoid muscle, being one of the muscles of forced inspiration, is contracted, so that tension on the neck while the muscle is rigid will be more likely to rupture it than when it is relaxed. The exponents of the simple traumatic theory with a subsequent microbic infection failed to have their theory substantiated by pathologic findings.

From the knowledge obtained from pathologic studies, it seems that the theory based on an ischemia of the sternomastoid muscle offers the most satisfactory explanation of the cause of congenital torticollis. This theory had its greatest exponent in Volcker.[3]

Frequency.—The frequency of torticollis may be judged from the following figures. Royal Whitman[8] states that in twenty-seven years of hospital records there were only 507 cases of torticollis as compared with 5,000 cases of club foot. Of 2,324 patients at the Evelina Hospital for Children, torticollis was found 9 times. The records of the Children's Hospital, Boston, for three years show 2,825 cases treated in the orthopedic outpatient department. Of these 44 were torticollis. These figures are misleading, as cases of deformity came to the children's clinic, so the percentage is high. Whitman reports 87 cases as being congenital out of his 507 cases. Of the 87 cases, 46 were females. The left side was affected in 28 out of the 87 cases. Of the 507 cases, 246 were females and 198 were males. Two hundred and thirty-six were on the left side. In 7 cases out of 55, there was a history of injury; in 48 no history was made of injury. In the 7 cases already referred to there was a history of injury accompanied by hematoma. Kempf[12] reported 37 cases of torticollis, with 24 in girls and 13 in boys. In this analysis it so happened that 50 per cent. were acquired torticollis and 50 per cent. congenital. Agnew believes that the sexes are equally affected. Dievenbach found 5 left torticollis out of 37 cases. V. Aberle discovered 111 cases of torticollis out of a clinic of 18,000 cases in Vienna. Hoffa reported that torticollis occurred in 49 per cent. of his cases, while Schantz found it in 9 per cent. of his cases. In the 111 cases reported by V. Aberle, 67 were right and 44 left. In the 100 cases analyzed by me, 51 were in boys and 49 in girls. Torticollis occurred on the right side 55 times, and on the left 45 times. Among the boys the right side was more common, occurring 35 times in comparison with 16 times on the left, while the left side seemed the more favorite situation with the girls, torticollis occurring on the left side 29 times as opposed to 20 times on the right.

Congenital torticollis may be seen at birth or may not be observed until the expiration of a few months of life. Some writers believe that it may be hereditary and that it frequently coexists with other malformations, such as club-foot and congenital subluxation of the hip, which deformities are considered to-day as possibly resulting from intra-uterine compression or from some initial malformation of the germ. It is also maintained by some that torticollis of the congenital type is closely related to difficult delivery arising from pelvic presentations, impactions of the head and fetal malposition. It has been found in this analysis that a history of delivery by forceps is often forthcoming, but by no means universal. This review of a hundred cases showed but one parent suffering from torticollis and failed to find torticollis coexisting with other malformations except in one case of cervical rib and two cases of supposed spinal defect. The history of labor in these cases was also interesting. Twenty per cent. of the congenital torticollis cases were of normal delivery, and only 14 per cent. gave a history of difficult instrumental delivery.

Diagnosis.—The diagnosis of congenital torticollis depends on a careful analysis of the history obtained and the elimination of all acquired types. It is remarkable how long a deformity may exist before being discovered by parents. In this analysis the average duration of the deformity before discovery, except when discovered in the first weeks of life, was twenty months, while two cases had gone four years without discovery. Both acute and congenital torticollis may be easily confounded with Pott's disease. Acute distortion with an affection of sudden onset, not preceded by stiffness or pain, such as characterizes tuberculous disease, with the head tilted toward the contracting muscle, is the type of case which is easily mistaken for Pott's disease. In this series there were two cases in which caries was suspected for a time. These cases were of acute and sudden onset, but not preceded by stiffness or pain. The head in each case was tilted toward the contracting muscle, while the chin rotated in the opposite direction. There was spasm and contracture, and tension on the affected muscle was very painful, but, if this tension was removed, the motion of the head was free. In Pott's disease, the spasm is always general and motions of the head are limited in all directions. In four of the cases analyzed a rachitic deformity simulated torticollis of the congenital type. In two of these cases a true congenital torticollis coexisted. Acquired torticollis is usually, in the early stages, at least, accompanied by localized pain and sensitiveness with an actual contraction of the affected muscle. The symptoms may soon disappear, leaving only the deformity. Congenital torticollis may not attract attention until the child supports the head or walks. It is difficult then to separate the acquired from the congenital form. In infancy the deformity may be marked with facial asymmetry and even by distortion of the skull. If the asymmetry is present at birth it increases with growth, and even in the acquired form it soon appears if the torticollis is not promptly corrected. In well-marked cases of long standing, whether of congenital or acquired origin, the face on the affected side is shorter and flatter and the skull shows signs of atrophy and deformity. Secondary distortion appears, round shoulders, scoliosis, bowing of the clavicles and lateral displacement of the head.

Treatment.—The treatment of congenital torticollis may be divided into manipulation, the use of mechanical appliances, and operation. Manipulation is successful in infants when there is very little deformity, the corrected position being maintained by means of some form of support. The mechanical treatment of torticollis, according to most writers, should be simple enough to permit removal of the appliance for daily manipulations. The operative methods should all embody the principles of complete severance of all tendons and fascial bands which prevent the correction of the deformity. The methods used are subcutaneous tenotomy or subcutaneous section of the sternomastoid muscle, which have no advantages commensurate with their increased danger. Lorenz[13] advised myorrhexis and forced manipulation with rotation in all directions to overcome any shortening of fascia or muscles beside the sternomastoid. Joachimstal[6] found it difficult and Reimer reported a death in a patient 16 years old. Brackett[14] reported collapse in a case during overcorrection. Open operation on the muscle is the rational method. The three sites of operative interference are, first, just below the muscle's insertion into the mastoid process; second, at its origin, just above the sternum and clavicle; third, in the middle portion of the muscle. The point of attack at the mastoid process is easily discovered, and owing to the facility with which the soft parts may be stripped back from the apex of the mastoid process, there is no danger of wounding the internal jugular vein or the nerve and the tendinous part of the muscle is left intact. The operation is easily performed and the resulting scar is left in the line of the hair, which is of great cosmetic value. The operation on the middle of the muscle presents many dangers. This portion of the muscle is thick and important vessels are in immediate contact with its under surface. The operation is difficult and the resulting scar is visible and may be unsightly. The operation which severs the sternal and clavicular portion of the muscle is the most popular in this country. Hoffa and Nové-Josserand[4] speak well of the partial resection of the muscle. Wullstein has partially resected the affected muscle and plicated or reefed the opposite muscle. Mikulicz[11] has nothing but good results to report from the total extirpation of the sternomastoid muscle.

---

[12] Kempf: Deutsch. Ztschr. f. Chir., June, 1904 (lxxiii).

The routine of the Children's Hospital has been the one followed in the large majority of the cases analyzed below. Three of the cases have had the mastoid incision, the rest have had the sternoclavicular incision, some parallel to the clavicle, some at right angles and a few by an oblique incision. The routine followed has been as follows:

Under ether the child is placed dorsally recumbent on the operating table, with the head twisted and the shoulder elevated so as to bring the offending muscle sharply into relief. The form of incision having been decided on and used, the dissection is carried down to the muscle at its tendinous portion, and all obstructing tissues are excised. The wound is closed in layers as tightly as possible, the skin approximation being as nearly perfect as can be. A collodion dressing is then applied over the skin wound, and the head held in an overcorrected position, while a plaster helmet is applied, which firmly holds this position. This helmet is then worn for two months, after which time the child wears a steel support, with a chin piece which maintains an overcorrected position of the head in its relation to the past deformity. The steel apparatus is worn for a year, being removed for purposes of massage and exercise.

Some writers insist on the daily removal of apparatus, for active and passive movements, beginning fourteen days after the operation. This has not been found necessary at the Children's Hospital to obtain good results. The use of Michel's clips in order to obtain the closest approximation of the skin, is strongly recommended, as is the oblique incision, which is better than the horizontal or vertical one, decreasing the danger of keloid degeneration of the scar. The after treatment of these cases varies with the different operators, but all agree that it is essential to success to maintain overcorrection for a certain length of time, and that some method preventing the offending muscle from shortening is necessary for from six months to a year. The results, as the tables show, are uniformly good, and those failures that must be reported were due either to the incompleteness of the operation or insufficient treatment after operation. After reviewing these cases, certain questions naturally present themselves.

Does torticollis occur in children who have less resistance to disease than other children? A comparison of the congenital with the acquired torticollis cases is interesting. If the greater average age, and therefore, longer exposure to disease, in the acquired type is borne in mind it will be seen that there is no unusual susceptibility in either group. The occurrence and frequency of disease in this list is only the normal frequency during the ages of childhood. The affections about the neck which would be expected are more frequently found in the acquired type than in the congenital type of torticollis.

Among the cases analyzed I found the complaints enumerated in Tables 1 and 2 had existed before the entrance of the patients to the hospital.

TABLE 1.—CONDITIONS EXISTING BEFORE ADMISSION

Disease	Acquired	Congenital
Ear trouble	7	1
Pertussis	28	13
Measles	33	25
Croup	1	1
Pneumonia	5	5
Rickets	3	1
Chickenpox	14	7
Scarlet fever	6	3
Diphtheria	5	3
Typhoid	1	1
Meningitis	1	0
Mumps	5	1
Malaria	1	1
Nervous	3	0
Rheumatic fever	3	1
Cervical rib	0	1
Tonsillitis	8	3
Adenoid hypertrophy	6	0
Bronchitis	1	1
Syphilis	0	1

TABLE 2.—AFFECTIONS ABOUT THE NECK

Disease	Acquired	Congenital
Ear trouble	7	1
Mumps	5	1
Diphtheria	5	3
Tonsillitis	8	3
Adenoids	6	0

In view of the reports wherein difficult labor has been attributed as the cause of torticollis, it is interesting to review the figures obtained (Table 3).

TABLE 3.—TORTICOLLIS ATTRIBUTED TO DIFFICULT LABOR

Status	Acquired	Congenital
Normal delivery	6	21
Not obtainable	12	12
Breech presentation	3	0
Transverse presentation	1	1
Foot presentation	1	0
Shoulder presentation	1	0
Instrumental delivery	12	16

The history of difficult labor with the danger of injury was found eighteen times in the acquired type of torticollis and seventeen times in the congenital, not obtained or normal in eighteen cases of the acquired type and thirty-three cases of the congenital.

In those cases in which the maternal observation may be taken seriously it is interesting to note the first symptom observed (Table 4).

TABLE 4.—FIRST SYMPTOM OBSERVED BY MOTHER

Symptom	Acquired	Congenital
General pain in neck	3	0
Torsion of neck	33	16
Stiffness of neck	15	1
Pain behind ear	5	0
Scoliosis	1	11
Tonsillitis	1	0
Tumor of the sternocleidomastoid.	0	19

---

[13] Lorenz: Wien. med. Presse, February, 1893.

[14] Brackett: Trans. Am. Orthop. Assn., 1897.

The absence of pain, as reported in the congenital type, is probably due to the inability of the parents to differentiate infantile pain of one cause from another, and is not of great comparative value. The presence of pain in the acquired type is not so prevalent as one would expect from published literature. The presence of tumor in the region of the sternocleidomastoid muscle was observed in ten cases of the congenital type. Torsion is by far the commonest symptom.

In view of the above figures it is of interest from a non-medical point of view to note what the parents believed to be the causation of the deformity (Table 5).

TABLE 5.—CAUSE OF DEFORMITY ACCORDING TO PARENTS' VIEW

Cause	Acquired	Congenital
Ear trouble	6	2
Rickets	0	1
Spinal meningitis	1	0
Birth injury	1	5
Rheumatism	1	0
Adenoids	1	0
Fall	1	0
Tonsillitis	3	8

Secondary deformity was found in many cases both of the congenital and acquired types (Table 6).

TABLE 6.—SECONDARY DEFORMITY*

	Acquired	Congenital
Facial asymmetry	6	15
Atrophy	4	10
Strabismus	1	0

* Scoliosis was present. In most cases the figures are very misleading, so are not given.

The atrophy, facial asymmetry and compensatory scoliosis seem to depend on the duration of the torticollis.

The last question to answer is always, What are the results?

Most writers report uniformly good results from their respective methods of procedure. A review of the literature confirms their claims. In all the cases analyzed, positively cured cases were 64 per cent.; 14 per cent. of the cases were lost from the clinic; in 16 per cent. of the cases not lost it was impossible to get data late enough to classify the result. One case was a failure after the first operation, but was cured by a subsequent operation. Of forty-five patients operated on and examined long enough after the operation definitely to classify them as successes or failures, thirty-nine patients were cured. The reasons for the four failures were of two sorts—either incomplete excision of the obstructing tissues, or insufficient after-treatment. Two cases were not true contractures of the muscle structure, but bony injury—unilateral displacement of the cervical vertebrae, which was not recognized before operation.

Operation definitely offers a cure for the deformity of congenital torticollis and the results are uniformly satisfactory.

272 Newbury Street.

The Insane in Switzerland and Spain.—The official figures for 1910 published by Koller for the four leading cantons of Switzerland show insane and feeble-minded to a total of 6 to 9.7 per thousand inhabitants. Koller accepts this as evidence that at least one in every one hundred persons there is mentally deficient or insane. The *Revista Clinica de Madrid* compares these with statistics in Spain, which show 1,000 insane in the asylums of the Madrid province, to a population of 900,000, that is, one in every 900 persons in the province is an inmate of an asylum.

THE CELLULAR FACTOR IN INFECTIOUS DISEASES *

DAVID RIESMAN, M.D.
PHILADELPHIA

The prevailing conception of an infectious disease is that it is due to the poison of a parasitic micro-organism. This conception seems to me inadequate, for it leaves out of account another and to my mind very important source of toxemia, at least in some of the infections, namely, the proliferation and disintegration of myriads of new cells.

Practically all writers have hitherto attributed the constitutional symptoms of infectious diseases to bacterial poisons, either exotoxins, i. e., secretory products, as in diphtheria and tetanus, or endotoxins—poisons inherent in the bacterial bodies, as in typhoid fever and tuberculosis. And many of the local changes likewise, such as the degeneration of parenchymatous organs, are ascribed to the same cause. Take diphtheria, for example: the general symptoms—fever, prostration, albuminuria, delirium, anemia—are supposed effects of the toxins; so are the circulatory changes, the cardiovascular weakness. The swollen glands and the false membrane formation are attributed to the local action of the toxin.

With regard to typhoid fever, the views are very much the same. The so-called constitutional symptoms of the disease—fever, headache, prostration, delirium, carphologia, intestinal tympany, and albuminuria—are attributed to the presence in the blood of the endotoxins of the typhoid bacillus. These same poisons are held responsible for the intestinal lesions, the changes in the lymph glands, the bone marrow and spleen, and the parenchymatous degeneration of the heart, liver, kidney and voluntary muscles.

In tuberculosis the symptoms are ascribed either to the tubercle bacillus, that is, to its poison, or to a mixed infection of this micro-organism with pyogenic bacteria. In other words, our present conception of the infectious diseases emphasizes solely the toxemia produced by the causative parasite. Is that view adequate? Is it correct? Before answering these questions, permit me to go back a little in time. A decade and a half ago while actively engaged in pathologic work, I chanced to make an autopsy at the University Hospital in a case of general carcinomatosis, the symptoms of which had closely resembled an acute infectious disease, the last phase being a comatose state. At the autopsy the peritoneum was found everywhere dotted with small whitish nodules, indistinguishable on naked eye examination from miliary tubercles. The discovery, however, of a primary cancer in the rectum and the characteristic histology established the carcinomatous nature of the lesions.

About the same period I had under treatment a man with miliary tuberculosis in whom the disease was with difficulty distinguished from typhoid fever. He died at the end of an acute illness of three weeks' duration, the autopsy revealing everything densely peppered with equal-sized, firm, gray tubercles.

These two cases made a profound impression on me—clinically so similar, etiologically so different, and the second so much like typhoid fever. I concluded that the three diseases must have something in common. The slightest acquaintance with pathology shows that the most striking thing they have in common is a tremendous cell proliferation. In a paper written at the time (in 1899) I made these cases the basis of a hypothesis which in its essential features is the same as that I wish to present here. Permit me to quote a few lines from this juvenile essay.[1]

---

* Read before the College of Physicians of Philadelphia, with lantern demonstration, Dec. 2, 1914.

> The death in miliary tuberculosis could not be explained by the destruction of tissue or even by the invasion of a vital part by the tuberculous process. The reason always given is that it is due to toxemia, through poisoning with the products of the tubercle bacillus. I would not deny that the bacillary poisons play an important rôle, but attention, so far as I know, has not been called to the part taken by the myriads of new cells that are added to the body in the course of two or three weeks. When we reflect that every living cell forms metabolic products, that cell multiplication is probably always accompanied by the excretion of certain materials, we must conclude that during the formation of the countless host of tubercles, with their infinite number of cells, a large quantum of metabolic substances is thrown into the circulation for the system to deal with as best it can; and when, under the influence of the bacillus, some of the cells break down, more soluble matters are washed into the blood. It seems but reasonable to conclude that the body cannot rid itself of that enormous quantity of metabolic products, even if this material were normal in character, and if it is, as we may justly assume, not normal, then the result can only be a profound intoxication. Add to this "metabolic toxemia," as I would call it, the bacterial toxemia produced by the bacillus, and the cause of death becomes clear.

For the moment I will leave out of consideration the carcinoma case and will confine myself to a discussion of miliary tuberculosis and of typhoid fever.

A miliary tubercle consists of a vast aggregation of epithelioid cells, together with some giant cells and many lymphocytes—cells for the greater part if not gether newly formed in response to the stimulus he tuberculous poison. The number of cells in a d sized tubercle is theoretically not beyond computation, but I know of no reliable estimate and for practical purposes the number is infinite. With regard to the tubercle bacilli, their number in a tubercle probably varies, but to all intents and purposes is also uncountable. When we consider the larger tuberculous areas, as in caseous pneumonia, both the cellular and the bacterial quantities must be expressed by the sign for infinity. I do not know how long it takes a tubercle to form, but it would seem that the cells multiply nearly as fast as the bacteria. In the course of two or three weeks there are thus added to the body in a case of miliary tuberculosis a quantity of new cells wholly beyond the power of the mind to conceive. These cells grow by utilizing the elements of the blood, chiefly the big protein molecule. In their period of active multiplication they take from the blood-stream what they need and cast back into it the unused remains. If the new cells are native to the place where they are formed then the cast-off products of their activity may be normal, though it is possible that they are formed in such quantity in a short time that the power of the system to deal with them is overtaxed. If we assume that since the cells are formed under pathologic conditions, they are not exactly like the old cells of their locality, then the possible harm done in their growth by abstraction and addition is even more readily conceived.

There is, however, another and probably more important factor to be taken into account in determining the fundamental causes of the symptoms of miliary tuberculosis. The newly formed cells soon die, by undergoing a peculiar change known as caseous degeneration. It is interesting to know how this is brought about. Some have ascribed it to the poison of the tubercle bacillus, others to starvation through inadequate circulation, and still others have held that the cells might be *ab initio* poorly endowed. The real explanation for the death of the cells is probably to be found in the newer theories of ferment action, especially in the theory of parenteral digestion advanced by Abderhalden. Abderhalden, as is well known, finds that if a foreign substance, let us say a foreign protein, which, were it introduced through the alimentary canal, would be digested there, is introduced under the skin or into the blood or anywhere except into the digestive tract, it excites at once the formation of ferments that break up the foreign protein into its so-called "building-stones." This dissolution of the protein by the appropriate ferments is a true digestion and since it occurs outside of the alimentary canal is called *parenteral digestion.* It is possible by physicochemical methods and by certain optical tests to demonstrate the presence of these proteoclastic ferments through their resultant products in the blood. The recent reports by Drs. Sailer, Schnabel and Williams have brought out the main points of the Abderhalden theory.

I have looked in vain in the English literature for a satisfactory rendition of the important terms created by Abderhalden to elucidate his theory, and have therefore endeavored to meet this lack by a series of new terms as shown in the following tabulation:

Abderhalden Term	Proposed Term
Körpereigen[2]	Idiosomatic
Körperfremd	Allosomatic
Bluteigen	Idiohematic
Blutfremd	Allohematic
Zelleigen	Idiocellular
Zellfremd	Allocellular
Arteigen	Idiogeneric
Artfremd	Allogeneric

A word about the derivation of these terms, in particular the prefixes, may not be amiss. "Idio" is derived from ἴδιος, own, proper, peculiar (οἱ ἴδιοι, friends). "Allo" comes from ἄλλος, other, foreign. Idiocellular and allocellular are, I confess, hybrids, but they are more euphonious, I think, than idiocytic and allocytic.

To return to the tubercle: As stated, the cells of the tubercle undergo a sort of digestion which in the ordinary case does not go on to complete solution of the tubercle. The failure of digestion to be complete, Jobling and Petersen[3] attribute to the presence of soaps which act as ferment-inhibiting substances. Under certain conditions not clearly understood — Jobling and Petersen believe that mixed infection is necessary—complete solution occurs with the disappearance of the tubercle. This is proved clinically by indubitable cases of cured miliary tuberculosis of the meninges and by the proved disappearance of even large tuberculous foci and masses in the lungs and peritoneum. In the removal of some of the products, phagocytes may be active; but the digestion itself is a chemical process.

[2] Gavronsky and Lanchester (Defensive Ferments of the Animal Organism, New York, 1914) in their otherwise very satisfactory translation of Abderhalden's book, use the rather cumbersome terms "in harmony with the body" and "out of harmony with the body" for the words Körpereigen and Körperfremd.

[3] Jobling and Petersen: Jour. Exper. Med., 1914, xix, No. 4.

We have then in tuberculosis myriads of cells undergoing parenteral digestion and in consequence throwing into the blood products that if not qualitatively are at least quantitatively abnormal. It is my belief, therefore, that in acute miliary tuberculosis and indeed in all other forms of tuberculosis, a large share, not yet measurable, in the production of the symptoms must be given to the substances liberated by the living and dying pathologic cells.

I will now pass on to typhoid fever. I may say at once that, in general, what I have said of tuberculosis holds true of this disease. The typhoid bacillus enters the body through the intestinal canal, gets into the intestinal lymphoid tissue, into the lymph glands, the bone marrow and the spleen and provokes in all of these places, in an exceedingly short space of time, a truly collossal proliferation of cells. I exhibit here several specimens of intestines in which Peyer's patches reveal themselves as large fleshy masses. The normal spleen weighs about 200 grams, the typhoid spleen probably five or six times as much. Even if some of this additional weight is blood, because of active congestion, the greater part is constituted by new cells developed in the course of a week or ten days.

The lymph glands of the mesentery are normally scarcely appreciable to sight. In typhoid fever they may be as big as walnuts. When we contemplate it, is not this increase in cells staggering to the mind —an increase quite on a par with the stupendous multiplication of the bacteria. This extraordinary cell proliferation is achieved by complicated processes in which, as Reichert[4] has just shown, the cells convert the stereo-isomers of the blood into their own specific proteins. The conversion involves such tremendous cleavages and reconstructions that as mere manifestations of dynamic energy they may be compared to the manifestations of radio-activity.

Adapting a further thought from Reichert, I might say that the typhoid bacillus, after entering the body, disturbs the physicochemical equilibrium and initiates a series of reactions that go on from step to step until the end of the process, a physiochemical equilibrium which is either recovery or death, is reached. The beginning of the process—the first step—absolutely and inevitably determines the end, a sort of predestination not dreamt of in John Calvin's philosophy. All the changes from the liberation of the typhoid poison to complete autolysis of the newly formed cells are produced by the action of appropriately geared ferments. These changes are all connected and in their totality they constitute the disease typhoid fever. Viewed from this aspect, the symptoms of typhoid fever are a composite of the bacterial and the cellular toxemias and are not the result of the typhoid toxemia alone.

Naturally it is difficult at this time to say what part of the symptomatology of typhoid fever is bacteriotoxic and what part is cellulotoxic, nor have I any clear idea how the problem is to be solved. Perhaps the Abderhalden test, employing spleen, bone marrow and lymphoid tissue as substrate, may show corresponding ferments in the blood. While that demonstration would not *ipso facto* be proof of toxic action, it would open the way to further research.

Pneumonia is another disease in which the bacterial toxemia has been overemphasized to the exclusion of everything else. It seems to me not at all improbable that some of the general symptoms are due to the exudate, independently of the bacteria.

Friedrich Müller and later Flexner[5] showed that the resolution of the exudate—the autolysis—is a fermentative process. Why may not active substances be liberated in this process, inasmuch as autolysis is an ideal example of parenteral digestion? It seems to me quite probable that the crisis is due to this factor rather than to bacterial antibodies. A study of the amino-acids in the blood, and animal experimentation with extracts of pneumonic lung, may help to solve the problem.

If anyone sufficiently interested will think over the remaining bacterial diseases, other examples of cellular toxemia will suggest themselves. There are, for instance, the ordinary pyogenic infections in which leukocytic infiltrations occur outside of the blood vessels. These infiltrations undergo digestive autolysis, whereby active substances may be turned into the circulation. The so-called Fochier's abscess (*abscès de fixation*) illustrates this possibility in an empiric way. That leukocytes may be active in the body for which they are *körpereigen*—idiosomatic—is shown by the recent observations of Moreschi[6] and of Rotky.[7] Both found that the leukocytes in leukemia destroy the power of agglutinin formation in typhoid fever and other infections. The effect of the Roentgen ray on the spleen in leukemia and other diseases, an effect manifesting itself by fever, prostration and metabolic changes, is another evidence of the possibility of cells from the individual's own body, in other words, idiosomatic cells, developing toxic power. It may also not be irrelevant to mention that Krehl[8] attributes the fever frequently noticed in pernicious anemia to elements derived from the disintegrating red blood corpuscles.

The interesting observations of Flury[9] are also in line with my hypothesis. Flury believes that the symptoms of trichinosis are in part due to the trichinae acting mechanically and to a poisonous substance which they contain; in part, however, to the chemical products that arise from the degradation of the invaded and damaged muscle tissue of the host.

With regard to malignant disease, the case I mentioned earlier in my essay finds a fairly satisfactory explanation if we assume that the theory or hypothesis of "cellular toxemia" is correct and of general application.

I have no doubt that the thoughts here expressed have in some form occurred to other men; yet I have looked in vain in medical literature for any allusion to the cellular factor in disease, apart of course from any local effects. The splendid Traité de Pathologie by Bouchard and Roger is, as far as I have been able to determine, entirely silent on the subject. It is true reference is made to the action of the lymphatic glands in infectious diseases, but chiefly in their mechanical relations as filters, or as I would call them, barrier-forts, as distributors of infection and as sources of phagocytes, not at all to the possibility that the products of the lymphoid cells, living or dead, may contribute an active "something" to the circulation.

On the basis of the theory or hypothesis here advanced a new classification of bacterial infections suggests itself. We may make two great classes:

A. The productive infectious diseases, characterized by cellular proliferation.

B. The non-productive infectious diseases, not so characterized.

To the first class belong tuberculosis, typhoid fever, and pneumonia.

In pneumonia the cells of the exudate may not be all newly formed. They may have been called forth from the cell depots in the blood and elsewhere. They are, however, new in their pulmonary site and in the Abderhalden sense are out of place.

To the non-productive bacterial diseases belong diphtheria and tetanus.

A closer study of this classification reveals an extremely interesting point, namely, that the infections classed under A, that is, the productive infectious diseases, are all due to bacterial endotoxins, or, in the sense of Vaughan, to split proteins, while those in Class B, the non-productive infectious diseases, are due to the soluble toxins and not to poisons contained in the bacterial bodies. Whether this is a general biologic law, I do not know.

In conclusion, I beg to express the hope that men devoting themselves to research, if they find anything suggestive in the hypotheses advanced, will test them by the experimental method.

SOME OBSERVATIONS ON THE NERVOUS AND MENTAL SYMPTOMS OF HEART DISEASE

JOSEPH IRWIN FRANCE, A.M., M.D.

BALTIMORE

In all our studies of disease processes it is imperative that we remember that we are always dealing with an organism and not with a mechanism, that this organism is a morphologic and physiologic unit, and that, therefore, there can be no change of a pathologic nature in one part which does not produce deviations from the normal throughout the whole. Particularly must it be borne in mind that pathologic processes, before they are discoverable by any physical sign, may, and generally do, produce marked changes in the nervous system of the patient. It is quite probable that the first effect of a nascent disease is the production of a nervous reaction which tends to inhibit the further development of the process. *Indeed, one of the chief* functions of the nervous system must be the overcoming of pathologic tendencies here and there and the maintenance of that fundamental equilibrium which constitutes health, in the face of the mechanical, chemical and biologic agencies which are constantly tending to disturb the perfect balance of physiologic forces. While, as yet, we are not able to understand them, we are compelled to believe that there are many nervous reactions, preserved and developed by natural selection, which are set in motion by those stimuli, which tend to produce a disease process, that these nervous reactions are of a conservative nature, and that without them the organism must quickly perish. A better *knowledge of these nervous reactions will go far* toward clarifying our understanding of certain puzzling phenomena of immunity and may throw some light on the obscure problem as to how mental suggestion can influence a morbid physical condition in a favorable manner.

The classic work of Head[1] on the "Mental Changes [illegible]sceral Disease" has not, I believe, [illegible] attention on the part of general practitioners and students of medicine.

Some time since, as a result of reading Head's article, and following certain suggestions of Dr. Stewart Paton, which were most valuable, I began a study of the nervous and mental symptoms of cardiac disease, and, while this work was not carried as far as I wished, I desire to present, in a preliminary way, some of my tentative conclusions. Head found that there were *two symptoms referable to the nervous system which* occurred quite constantly in cases of disturbed or broken cardiac compensation. First, a reflected pain along the distribution of the fifth nerve, and second, a mental and emotional abnormality, aside from any worry about the disease, characterized by depression, anxiety and fear, often with a sense of impending ill, and, further, that these emotional states occurred either with or without distinct delusions and hallucinations. It was my purpose to determine, if possible, whether these nervous symptoms could be made of practical diagnostic value, and whether the development of these emotional states in cases of cardiac irregularity could be made to throw any further light on certain disputed questions in connection with our knowledge of the emotion-producing mechanism.

We know that the mental state following a perception which is to cause an emotion, is followed by marked changes in the whole circulatory system, especially in the rhythm of the heart, the heart frequently being checked in its action, or momentarily paralyzed, this being followed by a rapidity and irregularity of action of varying degrees. The Lange-James theory of emotion, which has had many opponents, holds, as stated briefly by Ribot, that, in any emotional state, there is, "first, an intellectual state, then organic and motor disturbances, and then the consciousness of these disturbances, which is the emotion," or, as James says, "The bodily changes follow directly the perception of the exciting fact and our feeling of the same changes, as they occur, is the emotion." In view of this much discussed psychologic theory, it becomes most important to determine whether cardiac motor *disturbances, caused in a purely mechanical way, as* by a leaking heart valve, may act as a stimulus from below, as a certain intellectual state may act from above in producing an emotional state, and whether this emotional state, so caused, may bring about an intellectual state to explain it. *If this is possible, then* we have a complete reversal of the emotion-producing mechanism and very strong corroborative evidence in favor of the Lange-James theory. The observations of Head, which, as far as I went, I have been able to confirm, are of great value, for the reason that they give us new evidence on this point. As briefly as possible I desire to state some of the tentative conclusions which I have drawn from a study of Head's cases, as reported, and from observations on cases of my own.

AUTHOR'S CONCLUSIONS

1. A defective heart valve, producing cardiac muscle strain and irregularity, is sufficient to create a dis-

---

[1] Head: Brain, 1901, xxiv.

tinct emotional state of depression, anxiety and fear, independent, as Head says, of any worry about the disease. This emotional state, arising from a mechanical difficulty, resembles closely that arising from a psychic state, and the emotional state so caused may either remain vague and unexplained, or there may be induced delusions and hallucinations to explain it. One of my patients (Case 3) with mitral regurgitation suffered during the first stages of broken compensation from extreme depression, fear and irritability, but later became suspicious and obstinate and finally developed delusions of persecution and hallucinations. His delusions first appeared in the hypnagogic state, fading as he became fully aroused and attentive. Later, he came to hold them more tenaciously, and they finally became fixed. Further observations will prove, I believe, that persistent irregularity of the heart's action does, in almost every case, produce a mental and emotional state deviating in some important respects from the normal, which abnormality may be occasional, slight and transitory or so marked and permanent as to constitute a distinct psychosis.

2. The first mental symptoms of cardiac disease occur when the inhibitions of the higher centers are relaxing in the hypnagogic or in the sleeping state, and there is much to substantiate the old view that night terrors and nightmares are often caused by an irregularity of the heart's action. As the physical disturbance becomes more massive, either by increased intensity or chronicity, the mental abnormality is carried over into the partially or fully awakened state. One patient with aortic regurgitation and arteriosclerosis when trying to sleep would become greatly troubled with mild delusions of self-persecution and with self-accusation. This distress was frequently keen and would persist after he was fully awake. Often, to free himself from the annoying delusion, he would get up and move about, when the idea would become weaker, only to grow stronger again when he returned to bed. All heart patients should be questioned closely about their sleeping and dreaming, for it is quite possible that periods of failing compensation might be forestalled, in certain instances, if rest were instituted at the first approach of these marked nervous phenomena. There can be no doubt of the fact that any alteration of any of the normal physiologic rhythms, especially of the heart rhythm, exerts a profound influence on the mental state, especially during sleep. This being the case, it is evident that any system of psychic or dream analysis, as advocated by the Freudians, should take into consideration the condition of the circulatory apparatus and its functions.

3. There are cases of heart disorder which may long remain undiscovered by the attending physician because of his failure to properly study the nervous symptoms of his patients. Those disorders which are characterized by brief periods, occurring at long and irregular intervals, during which the normal action of the heart is more or less seriously disturbed, are very easily overlooked by the physician who places too much confidence in his stethoscope, which will reveal nothing in the interval between the attacks. A patient giving a history of occasional very distressing dreams, from which he awakes with a sense of oppression, should, if possible, be so placed as to be under observation during the night, when it may be found that the disturbed rest has been due to an attack of extreme bradycardia. I have seen one such instance, and here the occasional nocturnal attack of bradycardia was the only cardiac symptom for some time, although attacks during the day developed at a later period. Such cases show the importance of observations of the heart action during sleep, especially where there are unusual nervous phenomena. They also raise the very interesting question whether there may not be painful experiences in the somnolent state of a subjective nature induced by cardiac irregularity, caused by coronary and myocarditic changes, which for some time precede and may perhaps give warning of the symptoms of angina pectoris which are to develop later.

From what we know of the extreme sensitivity and quick response of the brain centers in the somnolent state to any alterations in the physiologic rhythms, we should expect to find such premonitory symptoms during sleep at the very beginning of the process of cardiac degeneration, and the question is worth further study.

4. The symptoms referable to the nervous system which we find in certain forms of heart disease are constant enough to be of practical value to the physician. The neuralgia of the fifth nerve and the scalp tenderness over the area of its distribution, as described by Head, is of such frequent occurrence that it is of some diagnostic and prognostic value in heart cases. In any case of heart strain, whether due to valvular lesion or prolonged functional overactivity, as in hyperthyroidism, this symptom may develop, and, in chronic valvular cases, the onset of neuralgia may precede a period of failing compensation so regularly that the patient himself learns that the pain is a signal that he must rest. It is, I believe, quite probable that a neuralgia of the fifth nerve is, far more often than has been generally supposed, a reflex visceral pain. In every case a thorough search should be made for a visceral cause, especially by a careful examination of the heart. In chronic heart cases the onset of neuralgic pains should always be considered an indication of the beginning of a period of disturbed compensation. It is possible that this pain may be the first and only symptom of seriously increasing heart strain in certain exceptional instances.

5. It is important to remember that many cases of fifth nerve neuralgia, and also many cases of neurasthenia with anxiety, fear and depression, especially in patients 40 or 50 years of age, may possibly be due to that condition of nerve strain which may be caused by a nascent cardiac disorder not sufficiently developed to be discoverable by physical signs. The long known favorable results of physical rest in many of such cases of functional nervous disorders might thus be explained if the theory is a sound one. Very much has been written about the far-reaching effect of ciliary muscle strain, and the profound influence of all forms of ocular trouble on the nervous system, and now we are just beginning to realize how necessary is the study of the influence of cardiac center, nerve and muscle strain, and compensation, perfect and imperfect, in the production of nervous symptoms.

Patrick[2] agrees with Dana,[3] that trifacial neuralgia is most apt to occur between the ages of 40 and 60, or in the "degenerative period of life," observations which are of great importance in this connection.

It is worth while to consider whether it is possible that the nervous and psychic symptoms described by

---

[3] Dana, C. L.: Natural History of Tic Douloureux, with Remarks on Treatment, The Journal A. M. A., May 5, 1900, p. 1100.

Head, constitute a complex conservative nervous reaction, preserved by natural selection for the protection of the organism, since pain and depression, by tending to limit activity, would in these cases exert a restorative influence. It may be that further careful study of the nervous symptoms of diseased states will furnish other examples of now unknown nerve reflexes which have for their purpose that same limitation of motor activity which is so often of such great therapeutic value.

Every individual is a network of more or less differentiated but intimately associated functions, and a disorder in any part or function, in its incipiency, and in its later irradiations, constitutes a natural experiment by which we can increase our knowledge of every part and function. What has already been learned by many able investigators of the interrelation of physical and mental states, has made possible modern psychology and psychiatry, but much more must be accomplished. Every physician should carefully investigate, as far as possible, the nervous and mental symptoms of his patients and make reports on interesting cases, and every general hospital should have a psychologic laboratory for the investigation of suitable cases. This preliminary and, perhaps, premature paper is offered in the hope of securing the interest and cooperation of others in this important line of work.

The following cases illustrate some of the above points:

ILLUSTRATIVE CASES

Case 1.—H., woman aged 52, married. Mitral regurgitation. March, 1904.

Twenty years before the patient had a severe attack of rheumatic fever, lasting all of one winter. Later, she had two attacks of pneumonia. Ten years ago she had a severe illness marked by fainting spells and dyspnea. In the winter of 1903-04 she went to a sanatorium with her husband, who was an invalid. She complained to the physician in charge that she suffered with severe facial neuralgia, but was told that it was only imaginary, and was advised to take plenty of exercise out of doors. She began walking several miles each day. The neuralgia became very severe after she began her regular walks in December. Early in March compensation was completely broken. Extreme dyspnea, bloody expectoration, edema of feet, soft blowing systolic murmur, with pulse 120, and, at times, very weak. All winter the neuralgia had been severe, worse at times, and when she was walking out of doors. The pain was over left face and forehead, over the back of the head, on the same side, especially behind the ear. It was very severe when treatment began in March. She was put to bed, given digitalis and purged and the neuralgia and heart action improved rapidly until the end of the third week, when the neuralgia disappeared.

I had this patient more or less under my observation for ten years after this attack, and while an invalid, with increasing disability, frequent periods of rest and extreme care prolonged her life. During this period neuralgic pains occurred at intervals and were always considered indications that a long rest in bed was necessary. This patient also had hallucinations, as described by Head, when the neuralgia was at its height. A little man in dark clothes would appear at the foot of her bed and look at her. She thought he was the pain and would say "Go away."

Case 2.—City Hospital (now Mercy). H., man aged 50, engineer, widower. Aortic insufficiency. Arteriosclerosis. Feb. 14, 1905. Dilated venules on face, lips cyanotic, neck vessels pulsate, emphysema, dilated heart, sounds irregular, with diastolic murmur at the base and systolic at the apex; disseminated arteriosclerosis; extreme dyspnea and orthopnea; Corrigan pulse.

Sleeps very lightly and says he knows the hour at any time in the night. Mental state at night as follows: He finds himself very much worried and reproaches himself for some piece of work he had left undone or had not done properly years before. He has a strong impulse to go and finish the work in question. The task is always a specific one in his past life, and there is an actual but faint delusion. He says, "I say to myself, that was long ago, that work. I have nothing to do with it now, and I get myself out of it [the delusion]." At these times he is probably partially asleep but is not sure. The idea has recurred over and over again at night. He says, "It is an idea, not a dream," and he is much distressed by it. To rid himself of it he would often get up and light his pipe, but even then sometimes it would persist and get stronger when he would return to bed. Pulse is weak, intermittent and every second or third systole is incomplete and not felt in the radial artery.

Case 3.—City Hospital (now Mercy). Feb. 28, 1905.

J. G., man aged 42. Mitral regurgitation, failure of compensation, psychosis. Nine years previously the patient had rheumatism; never the same since. Alcoholic; heart dilated; irregular; systolic and presystolic murmur; edema of feet; enlarged liver, 2 inches below costal margin; ascites.

New Year's night the patient had been drinking, when he was seized with dyspnea and pain over the heart; feared death. Now is very irritable, excitable and obstinate. Disobeyed directions because he had impulse to disobey. In this state before he came in. He was in a condition of mild resistance. Contradicts statements. March 10, sat up all night. Says, "Dropsy and pain slowly come up to level of lower chest at 10 a. m. and then slowly go back." Was irritable, anxious, emotional. Three days later became very restless and reticent, refusing to talk. Five days later he became suspicious and resentful, taking a dislike to one near him. He stares about in a nervous manner. He asked if he had been home since he had been in the hospital. Thought he had been moving at home, and asked when he would be paid a certain imaginary sum of money. About ten days later the idea that he was moving his furniture the night before seemed firmly fixed, except when he was fully aroused and attentive; but it became more difficult to make him dismiss his ideas and delusions. In the night he left his own bed for another and said he did not know he was doing it. His restlessness was due to a growing state of fear and anxiety and he talked vaguely about men and wagons coming to move him away. His heart symptoms improved but slowly and about a month after admission he became very troublesome, having developed well defined delusions that men were after him to kill him. He saw four men hanging over his bed. Tried to escape by jumping out of window. Begged to be saved, and insists that the delusions are real, pointing to his eyes and ears, saying that he knows what he sees and hears. He became more troublesome and the delusions of persecution more fixed until it became necessary to move him to the annex and put him under restraint. The delusions were very strong, and he seemed to be terrified, talking very confidentially and in pantomime. He was finally removed to Bayview Asylum, where, unfortunately, I lost sight of him.

15 West Mount Vernon Place.

An Anastigmatic Spectacle Lens.—Spectacle lenses hitherto employed have had the disadvantage of blurring the image at the edge of the lens, caused by the astigmatism of oblique pencils of light. Much improvement in this respect over the old flat lenses, with an angle of distinct vision of 16 degrees, was secured in the meniscus and Toric lenses, which latter gives an angle of distinct vision up to 52 degrees. A further improvement in the angle of distinct vision up to 60 degrees is said to have been developed by von Rohr in the laboratory of Zeiss of Jena, who succeeded in correcting for all foci the astigmatism noticeable toward the margin of ordinary lenses by computing the power of each lens and its correction separately. Lenses have heretofore been made with the same base curve on one side for all focal distances, the grinding to fit any special error of refraction being done on the other side. In the improved lens both sides are ground after the computation above referred to, with a resulting angle of distinct vision practically equal to that of the normal eye without moving the head.

HAY FEVER

ITS TREATMENT BY INJECTION OF A SOLUTION OF RAGWEED POLLEN

E. T. MANNING, M.D.
OMAHA

Hay fever as a clinical entity has been recognized since about the beginning of the nineteenth century. It was first regarded as a catarrh. Bostwick, one of the earliest writers on the subject, connected it with the heat and sun rays and called it summer catarrh. It was a natural transition for the disease to be later called hay fever, as it was thought, at least by lay minds, that the odor of hay caused an attack. Similarly, the appellation "rose cold" was given to that variety which seemed to follow from inhaling odor of roses. The first definite connection between the pollen of plants and hay fever was recognized by John Elliotson, in 1830.

In the United States it was early noticed that there are two distinct conditions inducing hay fever, quite similar in nature, but occurring at different times of the year—one beginning about the last week in May and lasting until the second week in July, and another commencing about the second week in August and continuing until the first week in October. The latter form, it was observed, was by far the more common in this country. The first clear description of the two disorders was given by Wyman, in 1872, who recognized the pollen of ragweed as one of the causative agents of the autumnal form. Blackley also believed that the symptoms of rose cold, the early form of the disease, were caused by the pollen of the *Graminaceae,* or grasses.

About the time of the researches of Pasteur and Koch, hay fever shared the fate of a host of other diseases, and the attempt was made to establish an infectious etiology. This obscured, somewhat, the importance of pollen as a causative factor, and it was not until 1896, when George Sticker published his classical monograph on hay fever, that the theory of pollen etiology assumed a definite, scientific character. Even Sticker, however, believed merely that the pollen carried an irritating parasite which would eventually be discovered. It remained for Dunbar definitely to convince the medical world of the specific action of the pollen.

The most recent experimental and clinical work on hay fever has been done by Karl Koessler[1] of Chicago, whom I shall extensively quote.

A definition of hay fever, in accordance with our present understanding of the condition, would be: an exudative catarrh of the conjunctival, nasal and tracheobronchial mucous membrane, produced in hypersensitive individuals by the sensitizing and anaphylatoxic action of the pollen of certain plants.

There is a certain condition, or group of symptoms, which closely resembles the true hay fever, but it is in only a slight degree related to it. I refer to the disease formerly known as hyperesthetic rhinitis. This resembles hay fever only in so far that it is a coryzalike attack induced by any form of irritation to the nasal mucous membrane. It may occur at any time of the year and does not carry with it the general constitutional depression which is so characteristic of the true hay fever.

As proofs of the etiologic relation between pollen and hay fever, or pollen disease, as it should more properly be called, the following may be offered:

First: If a few pollen grains, from one of certain members of the botanical group *Graminaceae,* such as rye, wheat, timothy, foxtail, etc., are inserted into the nostrils of a sufferer from rose cold, a typical attack of the disease is immediately produced. This may be done at any time of the year. Again, if a few grains of pollen from certain members of the botanical group *Ambrosia,* such as ragweed, golden-rod, asters, marigold, etc., are put into the nostrils of a patient subject to autumnal catarrh, an attack of the disease follows, even though the experiment be made in winter. Also, the action is specific, that is, pollen from *Graminaceae* will have no action on the autumnal catarrh man, and vice versa.

Second, and most conclusive proof:

It has been established experimentally that guinea-pigs can be readily sensitized to pollen protein by minute doses gradually increased, and, after a suitable incubation period, suffer a most severe anaphylactic shock on reinjection. Guinea-pigs were injected with serum from the blood of a patient suffering from autumnal catarrh, and later reinjected with a solution of 1 : 10,000 ragweed pollen, and a typical anaphylactic reaction resulted, thus proving that the guinea-pigs had been sensitized to pollen protein by that contained in the patient's serum. Control animals were not affected by the same dose of pollen protein.

I think we must conclude, therefore, that pollen from certain plants acts as a causative agent in at least a large majority of cases of hay fever. It has been found by experiment that of the members of the botanical group *Ambrosia* which produce this specific reaction the pollen from the ragweed is the most characteristic and representative. Consequently, ragweed is used exclusively to produce immunity reactions.

After the etiology of a disease is established, the next logical procedure should be to apply the knowledge gained, if possible, to therapeutic measures. The question at once arises, What is the pathogenesis of the condition? Accepting the fact that pollen protein is the causative factor in hay fever, what is deficient in the sensitive individual that allows the protein to act as a sensitizer? All explanations of immunologic phenomena are partially inadequate, but advance is made only by discarding parts of a given hypothesis and accepting those subject to proof. Consequently, some working hypothesis must be adopted.

The best explanation of the action of pollen in hay fever is that given by Koessler,[1] the substance of which follows: It has been known for some time that the bactericidal power of the nasal secretion is due to proteolytic enzymes. It is, of course, accepted that the pollen protein, at some season of the year, reaches the nasal mucous membrane of all persons. In most people the proteolytic enzyme present gradually splits the pollen, like any other foreign protein, into harmless products, proteoses and amino-acids. This cleavage occurs slowly, so that the poisonous group contained in every protein molecule is at any one time only in small concentration and is rendered inert, since the diffusibility is low. Thus, under normal conditions, the absorption of protein is exceedingly minute. However, there are certain conditions which interfere with the normal digestive function of the nasal mucosa, and in that case sufficient protein may be absorbed to lead to sensitization. One such condition may be a lessened nasal secretion associated with a lowered quantity of proteolytic ferment; or another may be a stenosis of the nasal canals through hypertrophied turbinates, leading to excessive accumulation of inhaled matter. It is conceivable that there may be a number of conditions which interfere with the normal nasal secretion. Whatever the cause of the disturbance of the power of the nasal secretion to break up complex protein molecules, the important fact is that, owing to this deficiency, there occurs a parenteral intake of foreign protein. This has the effect of injuring the epithelial cells of the mucosa and the endothelial cells of the capillaries in such a way that the mucosa remains permanently in a state of increased permeability for the protein; also, and most important, it brings about a new function of these cells, consisting of the production of a specific protective ferment directed against the specific pollen protein—in other words, the local tissue becomes sensitized. This, at first local, sensitization gradually reaches every tissue in the body, and all fixed tissue cells become sensitized, which is only another way of expressing the fact that all cells attempt to protect themselves by throwing off this specific proteolytic enzyme. The tissues first injured, however, retain this specific protective power to the highest degree. Thus these cells remain permanently in a state of sensitization, and when the protein again comes in contact with the sensitized area during the following season, the protein is absorbed unchanged and broken up in the body. The effects of this process depend on the degree of concentration and quantity of the poisonous fraction split off. The first symptoms are obviously local—there occur sneezing, itching and burning in the nose, eyes and throat, followed by vasodilation extending to inflammation with continued absorption. It may readily be seen how, if the process advances far enough, the bronchial mucosa may be affected, either directly or possibly through the blood, thus producing the dreaded asthma.

---

[1] Koessler, Karl: In Forchheimer, Frederick: Therapeusis of Internal Diseases, D. Appleton & Co., 1914, v, 671.

Now, how shall we make practical use of Koessler's theory and of our knowledge of the characteristics of the disease? Two ways are open. One may attempt to combat the disease by adding some substance to the organism which will neutralize the poisonous fraction of the split protein molecule, this constituting passive immunization; or one may try to develop in the tissue of the individual a substance which will neutralize the poisonous fraction, thus producing active immunization.

Dunbar elected to immunize passively, and his well-known pollantin is the outcome of his efforts. He injected horses with gradually increased doses of ragweed pollen, with the expectation that a specific antibody would eventually be formed in the serum in sufficient amount for practical use. He hoped that by injecting this antiserum into a sensitized human being, he would be able to neutralize the effect of the protein poison. Thus he assumed that the pollen protein acted as a true toxin. He was rewarded with a moderate degree of success.

Active immunization in pollen disease has not been attempted until quite recently. It is true that Dunbar, in his work in passive immunization, injected solutions of ragweed pollen in some of his assistants who were sufferers from hay fever, but the strength of the solution was so great that the results were very alarming, and he rejected this line of investigation. In 1910, Noon and Freeman in England and Koessler in America, unknown to each other, made the first attempts at active immunization. The English writers worked with the rose cold variety, caused by pollen from the grasses, this being the form most common in their country. Consequently, their results are of value to us only in so far as they prove the correctness of the principle involved. In a recent article, Freeman reports eighty-four cases with a so-called complete cure in 30.5 per cent.—the disease greatly diminished with almost complete relief in 34.5 per cent., slightly diminished in 24 per cent., and no effect in 11 per cent. He concludes that active immunization with a pollen vaccine, whether judged by statistics or the experimental method, has succeeded, and that the immunity seems to last for at least one year after treatment has been discontinued.

Koessler of Chicago first began his work in active immunization in 1910. He used ragweed pollen and treated only cases of the autumnal catarrh variety. He was the first to report definite methods of preparing pollen solutions, and to him must be given the credit of placing this form of the treatment on a scientific basis. He gave injections both in a prophylactic way, before the appearance of the hay fever symptoms, and after the disease had been established. His results correspond closely with those of the English investigators. He reports 10 per cent. absolute cures, 70 per cent. markedly improved subjectively and objectively, 12 per cent. subjectively improved, and 8 per cent. not affected.

My own experience with this method of therapy began in August, 1914. I was unable to obtain any ragweed pollen until the time of the flowering of the plants. Consequently, my attempts at immunization have been confined to those patients who were already suffering from the disease. I feel certain that the desirable course is to give the injections before the symptoms appear, and thus to attempt to establish the immunity before exposure to the pollen. I found it exceedingly difficult to gather the pollen, owing to its extreme lightness. The plants were picked and placed in water over night, in a room where the air was not moving, and then with a camel's hair brush, the fine yellow pollen grains were brushed off into a dish. I obtained pollen from two varieties of ragweed, *Ambrosia artemiseaefolia*, or the common dooryard form, and *Ambrosia trifida*, or giant ragweed, which grows along marshy places.

I followed the technic of Koessler, with some slight modifications: Ten mg. of pollen from each variety is triturated with sterile silicon in an agate mortar. Twenty c.c. of a sterile salt solution ten times stronger than a physiologic is then gradually added and thoroughly shaken. The suspension is placed in the incubator for twenty-four hours and again shaken. The mixture is then centrifuged at a high rate of speed and the supernatant fluid pipetted off. This solution is a dilution of 1:1,000, and from it all others are prepared. First, it is diluted ten times with sterile distilled water to which has been added 0.25 per cent. phenol (carbolic acid). The salt solution is then a physiologic one, and is a dilution of 1:10,000. This dilution and all lower ones are unstable, and deteriorate by progressive proteolysis into a toxic product within ten days. The concentrated 1:1,000 solution is more stable and will keep, on ice, for about three weeks. It is needless to say that all manipulations must be carried on with aseptic precautions. I have made it a rule never to inject a solution until after plating on agar.

The unit of pollen toxin adopted by various workers has been of different sizes. I have adopted as a unit the amount of protein contained in 1/1,000,000 gm. pollen, or that contained in 1 c.c. of a dilution of 1 : 1,000,000.

I treated twenty-one cases; fourteen were objectively and subjectively relieved; in the other seven the treatment was incomplete for one reason or another. Two of these seven showed no reaction, either good or bad. Four more were certain that their attacks were lighter. One patient was undoubtedly made worse, a result which I think was due entirely to a mistake of judgment on my part in giving her a large dose without gradually working up to it. Three of the cases had a bad asthma complicating. Two of these were completely under control and the other was much relieved.

I feel that I lost much valuable time in the early part of the treatment in being too cautious, as I realized the possible alarming effect which might be produced by too large a dose of the vegetable poison. I believe a dose larger than seventy-five units cannot be given without producing unpleasant symptoms.

In fourteen cases in which a positive result was obtained, I observed this striking occurrence in each case: After a dose was given sufficiently large to obtain relief, the freedom from symptoms lasted only from two to five days, depending on the severity of the case. Then the symptoms returned, although they usually were not so severe. Another dose of the same size being then given, relief was again obtained. One is impressed with the fact that the immunity conferred was only of a transitory nature.

It is difficult to determine exactly what should be designated as a cure. Many years ago a great medical philosopher, who was no pessimist in regard to treatment, gave as an aphorism, "Nothing ever gets completely well." It is true that there are few disease processes which do not leave their impress on the organism in some chemical, anatomic or functional alteration. Our desire to apply the word "cure" to a treatment probably arises from the effort to keep pace with the medical charlatans who are only too anxious to guarantee so-called cures. So in hay fever—a disease which is extremely susceptible to all the changes in nervous control of the individual, with some symptoms exceedingly vague and influenced to a large extent by the imagination—it is very difficult to determine just what part this or that remedy plays in modifying the disease process, and in thus assisting in a cure.

Statistics concerning the effect of a therapeutic measure are decidedly unreliable as a guide. But few persons, and these only in rare circumstances, act on statistics alone. They act rather on experience, either their own or of others. When they do this they are on surer ground than when they rely on bare figures alone.

I have tried to be conservative in my interpretation of the results I obtained, but a very distinct impression remains that the injections have been of decided value in ameliorating the distressing symptoms. I shall expect more definite favorable results from treatment begun before the disease starts. I feel that much of the success of the treatment will depend on the judgment exercised to meet particular symptoms in each individual case. I have quite certainly satisfied myself that the treatment cannot be rigidly applied the same way to all cases. The known principles governing immunity, which are all too few, must be thoroughly understood and applied.

I am sure that Koessler was fully warranted in issuing the warning that much harm may result from the treatment unless certain precautions are taken, namely, the solutions must be sterile, they must be fresh, and they must be, as far as humanly possible, of uniform potency.

PSEUDOMYXOMATOUS CYST OF THE APPENDIX WITH CALCIFICATION OF WALLS

REPORT OF CASE

H. H. OGILVIE, M.D.
SAN ANTONIO, TEXAS

In referring to current and to text-book literature[1] I find that pseudomyxomatous cysts or retention cysts of the vermiform appendix are themselves a rarity or else are rarely reported. Hartman and Kindley[2] have summarized the former reports, the text-book accounts and the pathology of the condition. The formation of the cyst is, no doubt, due to chronic inflammation, occlusion and obliteration of the lumen of the appendix at or near the proximal end, together with a twisting of the appendix and subsequent adhesions to the surrounding structures. The history of the case which I wish to report coincides exactly with this theory of causation. Only one text-book of pathology out of the many which I consulted made any mention of calcification or calcareous degeneration of cyst walls. This pathologic change is the distinct feature of my case.

History.—White man, aged 22, railroad brakeman, 6 feet tall, weight 185 pounds, with negative family and personal history, was in Corpus Christi, Texas, four years ago, Sept. 10, 1909. That night he was feeling well and ate a hearty supper; later in the night he consumed a great quantity of olives. The next day he had an attack of acute indigestion which was diagnosed cholera morbus. This illness lasted for ten days; he complained at that time of pain in the right side in the region of the appendix, nausea, vomiting diarrhea and fever, which gradually subsided. After this the patient was well for three years. In the fall of 1912 the patient had a similar attack of gastritis, pain in the right hypochondrium and fever. A diagnosis of acute appendicitis was made by the physician who saw him at that time, but an operation was deemed inadvisable just then for some reason. Since this attack the patient has been well and strong and has suffered no inconvenience other than obstinate constipation. He complained, however, of something solid "tapping him on the inside" at the appendiceal region while he followed his daily work.

Oct. 3, 1913, the patient had a sudden chill, fever, aching limbs and a bronchitis, together with the additional symptoms of acute appendicitis. In other words, he had acute influenza complicated by acute appendicitis. His greatest pain was in the high appendiceal region.

Examination.—Palpation revealed a hard, irregular mass 1 inch above and 2 inches internal to McBurney's point.

[2] Hartman, Henry, and Kindley, G. C.: A Case of Pseudomyxomatous Cyst of the Appendix, The Journal A. M. A., June 6, 1914, p. 1795.

Roentgenoscopy revealed a calcareous mass of rather irregular outline to the right of the fourth and fifth lumbar vertebrae. The roentgenogram clouded the picture of the case, and the diagnosis hinged between a calcified cyst of the appendix and a ureteral calculus.

Operation.—An anterior incision was made over McBurney's point. After breaking down of the adhesions, a hard calcified mass was delivered; this proved to be the appendix. An ordinary appendectomy was performed. Examination revealed a pseudomyxomatous cyst of the appendix, whose walls had undergone calcification. The length of the mass removed was 2½ inches and the breadth 1½ inches at the widest point. The walls of the cyst were calcified almost in entirety; the part not calcified was thickened, tough, fibrous tissue, and the muscular elements were scant. The cyst contents showed a mixture of pus and mucoid material. The base of the appendix contained the mucoid substance while the distal portion showed pus. The gross specimen was submitted to the Pathological Department of the University of Texas at Galveston, and the foregoing diagnosis corroborated.

THE RELATION OF PITUITARY DISTURBANCES TO PARANOIDAL TRENDS

HENRY W. KEMP, M.D.
NEW YORK

The more recent writings and monographs on the endocrine glands have afforded the medical profession a most fascinating field for study and experimentation. As the result, the somatic manifestations of secretory and other disturbances of these glands are fairly familiar and will not be dwelt on here.

In addition, however, to the pathognomonic somatic symptoms, disturbed functioning of the ductless glands gives rise to marked psychic phenomena of varying character and intensity, from idiocy and mental lethargy to the most agitated and apprehensive states. Thus far, I believe, these phenomena have failed to receive the attention which should be accorded them, and a great field is here opened to our American psychiatrists.

While the psychotic symptoms vary with the various glands affected, and in the same glandular disturbances in various individuals, yet in all cases I have seen of pituitary disturbance (not a large number, it is true), the mental symptoms have invariably been paranoidal in character.

If this statement be universally true, the possibility of paranoidal ideas being due to physical or chemical disturbances of the hypophysis has occurred to me. In the literature on the subject I have not as yet seen such a suggestion.

Our state asylums yearly treat about two hundred thousand cases of insanity. It would appear, should the superintendents of such institutions concur in their advisability, that a number of experiments on the treatment of paranoidal conditions might be advantageously conducted. The proof or falsity of the idea presented above could be demonstrated, and the value or worthlessness of suitable glandular therapy in this connection determined.

This suggestion is given for what it may be worth; and, should no connection be demonstrated between paranoidal ideas and pituitary disease, the results from a large number of carefully studied cases by such competent men would well repay them and the profession generally for the time and energy expended.

855 Fresh Pond Road, Borough of Queens.

CASE OF UNUSUAL TOLERANCE TOWARD BELLADONNA

Sidney H. Adler, A.B., M.D., New York

History.—D. P., married woman, aged 31, first seen May 20, 1914, complained of severe cramp-like pains in the abdomen. She had been taking heroin hydrochlorid hypodermically for three years, owing to severe pains in the kidney regions, following several operations, and she desired to take some treatment for the cure of the habit.

Examination.—When first seen she was fairly well nourished. The heart and lungs were negative. Blood pressure was 115-85. The urine was negative. Nothing abnormal could be ascertained from abdominal palpation. The entire area around the kidney region was painful to touch. Otherwise the entire physical examination was negative.

Treatment.—The patient was prepared for the treatment by rest in bed, catharsis, and reduction in the dose of heroin to which the patient was accustomed; that is, we gave her the amount she said she was taking, and found that attacks of sneezing started toward the time the next dose was due.

May 24, the Townes-Lambert treatment was instituted. The mixture, tincture of belladonna (15 per cent.), 20 c.c., fluidextract of xanthoxylum, 10 c.c., and fluidextract of hyoscyamus, 10 c.c. was administered every hour, starting with 6 drops and advancing until 8 drops were given every hour. The dose was then advanced until it reached 16 drops. When this dose was reached, there were no effects noticed and orders were given to advance the dose until physiologic effects were evident. The dose was then run up until the patient was taking 48 drops every hour. To reach this limit the dose was increased by as much as 2 to 4 drops every few hours. Not understanding why such a great amount of belladonna and hyoscyamus could be tolerated without any symptoms except slight dryness of the throat, I called up the Townes Hospital and was told that the only suggestion they could make was that we had not a mixture containing tincture of belladonna 15 per cent., but that it contained only the U. S. P. 10 per cent. tincture. They were kind enough to furnish us with some of the mixture used in their hospital, and the patient was started on advancing doses, the first being 6 drops, and rapidly advancing doses had again no effect on the eyes, throat or skin. The mind was clear throughout, but instead of feeling drowsy, the patient had no desire to sleep. No increased irritability of the brain was noticed, nor was her speech confused at any time. For only one day did she need any aid to vision; in fact, to keep her quiet we gave her the paper and books to read.

When the dosage was again carried to 48 drops, it was held there and then slowly reduced to nearly normal dose.

The compound cathartic pills were administered as directed by Lambert.[1] Treatment was discontinued June 3, the patient having had but one dose of heroin in four days, and then only a single dose of 1/24 grain.

Tonic treatment, started toward the end of the treatment, was continued, and until the date of writing the patient has not taken any drug.

Comment.—This case was complicated by the severe pains in the kidney region, which persisted and necessitated examination.

The patient was referred to Dr. H. D. Furniss, who reported the kidneys normal, with no obstruction in either ureter or bladder. The only abnormality shown was in the ureter, which was being deflected by adhesions caused by previous operations. The kidney was fixed in a low position, the pelvis being at a level with the third lumbar vertebra.

Because of the great pain caused by the collargol injected into the ureter, the patient was given several doses of morphin sulphate, ¼ grain hypodermically.

The pains persisted through the greater part of the summer, but with returning strength and outdoor exercise they became less frequent.

---

[1] Lambert, Alexander: The Obliteration of the Craving for Narcotics, The Journal A. M. A., Sept. 25, 1909, p. 984.

The dose of the mixture does not depend on the amount of drug taken by the patient, nor on the size, weight or length of time that the patient has been under the influence of the drug. Some patients, I was informed at the Townes Hospital, are under influence of the mixture while taking from only 2 to 4 drops, the average dosage being about 12 drops, and the greatest amount administered to any patient *has been 30 drops.*

It is impossible to state with precision the exact quantity which may cause death, belladonna with its component, atropin, being one of the substances whose effect, varying in different cases, seems to depend on special constitutional tendencies or idiosyncrasies of the individuals. Some persons can take a comparatively large amount with impunity, while others scarcely bear a very moderate dose without exhibiting unpleasant symptoms.

This case is reported because of the great tolerance to belladonna, the patient taking about 1 ounce of tincture of belladonna, 15 per cent., within twenty-four hours, for several days without toxic symptoms.

ROUNDWORM WITHIN THE BODY OF A TONSIL

A. B. MIDDLETON, M.D., PONTIAC, ILL.

M. A., a girl, aged 8, of German parents, referred by Dr. E. M. Adams of Gridley, Ill., gave the following *history*: She was one of four children, all healthy; the father and the mother were the same. The parents say that the child was a fat girl till 2 years of age, at which time she had chickenpox, and has not been well since. When Dr. Adams first saw the child she was pale, anemic, thin, very much undersized for her age, with an adenoidal expression, etc. The mother says the child has had regular bilious spells for two or three days at a time once every three weeks; she never had sore throat, but is a constant mouth breather.

Both tonsils were enlarged and submerged, the right paler than the left. The child was operated on in the usual manner under a general anesthetic for the enucleation of the tonsils and adenoids. The child was on her left side, the right tonsil being in plain view. As the snare wire began to tighten, the tonsil was seen to rupture into the cavity. At once a whitish something began to present itself. Several visiting physicians, who were present, were invited to see what was thought to be an abscess cavity or large crypt empty itself of retained concretions; but the supposed concretions proved to be a roundworm that coiled itself on the roof of the mouth, making a spectacular demonstration for those present. After the worm had been removed carefully, the tonsil was taken out in the usual manner and divided, showing a cavity lined with a glycerin-like substance, which had been the home of the worm possibly for several years. Under a low power lens it was easy to see that it was a female *Ascaris lumbricoides*. These cases may not be unusual, but this is the first case I ever knew about in which a roundworm has been found in a tonsil.

The worm was about 1¼ inches long with a distinct head, and the tonsil was about the size of a medium-sized olive. Dr. Adams wrote me later that the child does not have the so-called bilious spells, enjoys good health, has a lively disposition and is getting fat.

Hat Pin Injury.—E. W., boy, aged 7, was riding in a buggy with his mother, January 24, and in some manner the point of her hat pin penetrated his right eyeball. For the next three or four days, the father used some medicine in the boy's eye that he had obtained from a physician for an inflamed eye of his own some months previous. January 29, I saw the boy for the first time; there was a large corneal ulcer completely covering the pupil and also a pronounced traumatic iritis. As far as I could determine, the lens itself was not injured. Even if the eye makes an uneventful recovery, there is practically total loss of vision because of the large ulcer.—E. A. HUNT, M.D., Burlington, Iowa.

PRACTICAL PHARMACOLOGY *

(Continued from page 588)

VII

B. DEPRESSANTS: 5. OF THE HEAT CENTERS

ANTIPYRETICS AND ANALGESICS

The drugs of this group are classified conveniently *under this heading, though they are seldom used* therapeutically for the reduction of temperature alone. The discussion of their actions will be facilitated by a brief consideration of the regulation of body temperature in health and in fever.

There is no known anatomic center for the direct regulation of the body temperature, but there is certainly a coordinating mechanism, in addition to any local mechanism in the skin, whereby the temperature of the body is maintained both in health and in fever, and reference to this mechanism is made when the heat-regulating centers are mentioned.

The efficiency of the heat-regulating mechanism is shown by the fact that the production of heat may be increased 60 per cent. by taking food, or during severe exercise, without causing a rise in the temperature of the body.

Fever results from a change in the heat-regulating centers whereby they appear to economize the heat loss, so that while with any increase in the heat formation there is normally a compensating heat loss, during fever a slight increase in heat formation is attended with some increase in the loss, but not enough to prevent the temperature from rising to a given degree.

The centers do not lose control of the regulation, otherwise the temperature would continue to rise indefinitely, and in fact, during fever the centers are more sensitive to external changes in temperature and to the influence of drugs than normally. This increased sensitiveness may be looked on as the effect of stimulation of the centers by drugs or disease products. We may look on the antipyretic actions of the drugs of this group therefore, as depressant to the heat-regulating centers, preventing them from maintaining the higher temperature, which then returns toward normal. This conception led to Schmiedeberg's classifying the antipyretics of this group as fever narcotics.

The antipyretic effect of quinin is due mainly to diminished heat production through its peripheral actions; the other antipyretics of the group lower the body temperature through their central action which increases the elimination of heat, but quinin also has some central action, and the other antipyretics lessen heat formation, so that their actions differ mainly in degree.

It seems probable that fever may have a protective value in infectious diseases, since it appears to favor the formation of antibodies, and it is no longer held that hyperpyrexia is responsible for many of the pathologic changes which are found at necropsy, and which were formerly attributed to the febrile temperature which was therefore considered so dangerous.

---

* This is the seventh of a series of articles on useful drugs—on practical pharmacology for the general practitioner. As soon as completed, these articles, elaborated by additional subjects, will be published in book form.

It was owing to this erroneous view that the antipyretics had an enormous vogue soon after their introduction, and for a time there was intense activity in the search for new and better drugs of this type.

QUININ

It is commonly stated that the therapeutic use of cinchona, from which quinin is prepared, began with the treatment of the Countess of Chinchon in Peru in 1638, during an attack of malaria. The Jesuits employed it in the treatment of malaria in Europe, and from the foregoing circumstances it was variously called, Chinchona bark, Cinchona, Peruvian bark, Countess' bark, Jesuits' bark or simply "the bark." At present nearly all of the quinin of commerce is obtained from cinchona cultivated in India and Java.

Quinin is a protoplasm poison and is capable of destroying various forms of animal and vegetable cells. While it exerts its toxic action on such a variety of structures, it is extraordinarily active in destroying certain low forms of life. In 1867 Binz observed that in weak solutions it killed the paramecium of hay infusion at once, and that in very dilute solutions (1:20,000) it exerted a markedly toxic action on them, though they were much more resistant to the action of other poisonous alkaloids such as morphin and strychnin. These observations led Binz to the conclusion that malaria is due to a parasite which quinin is capable of destroying readily. The correctness of this conclusion has been abundantly proved, of course.

Since the great value of quinin in the treatment of malaria depends on its destructive action on these micro-organisms, it may be worth while to present briefly the more important facts concerning their presence in the human body.

It is known that when the anopheles mosquito bites a patient suffering with malaria it takes the malarial fever organisms into its stomach with the blood which it draws; that this blood contains asexual forms and smaller numbers of others which take on the sexual form and after passing through a cycle in the body of the mosquito, are injected with the saliva into the body of a person whom the mosquito bites later. These organisms, known as sporozoites, enter the blood and attack red blood-corpuscles, assuming a form which then multiplies in the blood. The sporozoite undergoes segmentation, and with the breaking up of the red blood-corpuscles and discharge of the young parasites into the blood there occurs a paroxysm of malaria, that is, a chill followed by a hot stage, presumably due to the discharge of toxins into the blood-stream.

Quinin is most destructive to the young parasites at the time they are discharged into the blood-stream, and it is important that the administration be so timed as to secure a sufficient concentration in the blood during the time that sporulation occurs. Unfortunately, in addition to the forms which quinin destroys readily, there are others which are more resistant and which may survive to become sources of infection through the anopheles.

The testimony of eminent authorities appears to be contradictory concerning the capacity of quinin to prevent an oncoming paroxysm. Thus Osler states that quinin has no power to prevent an oncoming paroxysm which attends segmentation; Ricketts states that quinin given some hours before the time of an expected paroxysm prevents segmentation and thus prevents the paroxysm. This is in accordance with the teaching prevalent in some malarial districts, and there can be little doubt that a large dose of quinin given four hours before the time of the expected paroxysm may prevent it, but it has no influence on a paroxysm which is just beginning.

The action of quinin on the blood and its capacity for causing hemoglobinuria have been the subject of much discussion. Quinin even in dilute solution is known to be capable of destroying both the red and the white cells of the blood in vitro. Hemoglobinuria has been observed frequently after the administration of quinin, which was therefore believed to be its cause. Hemoglobinuria may occur during malarial fever, however, without the administration of quinin, and the view now held by the most eminent authorities is that quinin is not the cause of the hemoglobinuria which sometimes follows its use in malaria.

It should be remembered that washed corpuscles behave differently toward various drugs in vitro from the way they behave when those drugs are injected directly into the blood-stream. For example, saponin destroys red blood-cells suspended in normal salt solution, but when a solution of saponin is injected into the blood-stream directly, the saponin is fixed by the cholesterin present in the blood and the red blood-cells escape injury. Binz states that 1 gm. (15 grains) of quinin hydrochlorate in 10 per cent. solution may be injected intravenously without causing injury to the blood. There would then be 1 part of quinin to about 5,000 parts of blood.

Very small amounts of quinin are capable of increasing the force of muscular contraction, but slightly larger amounts decrease the force and efficiency. This is of interest with regard to the action of quinin on the heart when large doses are given, and also with reference to the action on the uterus when quinin is used to increase the force of uterine contractions during labor. One can understand why it should sometimes have the desired effect and why it should sometimes fail, owing to the difficulty of adjusting the dose with precision. It seems probable that the action of quinin will be useful when induced at such a period that a few powerful contractions will suffice to expel the fetus; but if labor is not nearly terminated the induction of a few powerful contractions may be followed by weaker ones, and labor may be prolonged through its depressant action. Fortunately, it does not cause spasm of the uterus as many of the oxytocics do.

Quinin is not used for its action on the musculature of the heart, but it is of toxicologic importance. It is also of interest to note that cinchonidin is more poisonous to the heart and much less actively destructive to the malarial fever parasites. Cinchonidin was formerly much cheaper than quinin, which it resembles closely in appearance and in physical properties, and for which it was often fraudulently sold.

Quinin lessens the action of enzymes and of oxidation and it causes a diminution in the amount of heat formed in the body through its lessening metabolism by its action on muscles and glands. With small doses this diminution in the amount of heat formed does not cause a fall in the body temperature during health, because the heat-regulating centers compensate for the change by causing a diminished loss of heat. During fever quinin acts as an antipyretic (aside from its specific action in malaria), partly through this diminution in heat production and partly by depressing the heat-regulating centers. It is said that this influence in diminishing metabolism is useful in certain fevers by preventing an undue loss of protein but it is probably of little value in this way.

Quinin has only a slight analgesic action, and this has a limited field of application.

TOXICOLOGY

The prolonged use of quinin may result in injury to various organs, but the heart, the central nervous system, the gastro-intestinal tract and the kidneys usually suffer most in such cases.

Moderate doses of quinin commonly cause ringing in the ears which lasts for some hours; large doses may cause partial or complete deafness, the effect being brief as a rule, but occasionally permanent.

Dizziness, headache, nausea and vomiting with disturbances of the circulation and respiration occasionally result, and it may cause cardiac failure; disturbances of vision are rare. Skin rashes are fairly frequent.

The average fatal dose of quinin probably lies between 8 and 15 gm. (from 120 to 240 grains), much depending on the rate of its absorption.

ABSORPTION AND EXCRETION

Even the least soluble of the salts of quinin are absorbed fairly readily from the gastro-intestinal tract. In order to secure the more rapid action the more soluble of its salts are sometimes recommended, but there are occasions when an insoluble salt is preferred because of its less pronounced bitterness. The use of the sulphate in the United States affords an example of the force of habit, the hydrochlorate, which is used almost exclusively in England, being much more soluble.

Thayer states that the rate of absorption and its total amount vary widely with the solubility of the salt used and the form in which it is administered, absorption being retarded when it is taken with the food. In view of the importance of securing the absorption of quinin at such a rate that the requisite amount will be present in the circulation at the time of segmentation of the parasites, it is unfortunate that our knowledge of the subject is so imperfect.[1]

It is probable that too much importance has been attached to the influence of the degree of solubility of the salts of quinin on their absorption, and too little attention to the selective capacity of the gastro-intestinal tract for absorbing them. The question is in need of further investigation. The utmost care should be exercised to secure aseptic conditions, when a salt of quinin is injected subcutaneously or intramuscularly, because of its destructive action on the tissues, which leads to abscess.

Quinin usually begins to appear in the urine shortly after its administration, and almost the entire amount may be excreted within two days. A part is excreted into the stomach after its subcutaneous injection.

THERAPEUTIC USES

The chief therapeutic uses of quinin have been suggested in the foregoing discussion, and the subject requires only brief consideration here.

Quinin finds its principal field of usefulness in the treatment of malaria, being one of the few directly curative agents in the materia medica.

It is a matter of little importance, so far as the action is concerned, which of the salts of quinin is used, provided the one chosen is so administered as to secure absorption at such a rate that the blood will contain the quinin some hours before and during segmentation, or when segmentation would occur if it were not prevented by the drug.

Cinchonidin has been used in some cases when an idiosyncrasy, real or fancied, prevented the use of quinin, but the slight antimalarial action and the toxicity of cinchonidin render it an unsatisfactory substitute for quinin.

Quinin is an active antipyretic, and while it may be of some value during protracted fevers, such as typhoid, by reason of its lessening metabolism, and thereby preventing excessive destruction of protein, it is not certain that this advantage will outweigh its disadvantages in such conditions.

Its use during labor has been mentioned. While it does not cause spasm of the uterus, it is not always successful in facilitating the expulsion of the fetus.

Small doses may be used as a bitter for improving the appetite and digestion; large doses have an opposite effect. It is sometimes used at the inception of a cold, but its value in such conditions is problematic. It is also used as an antipyretic and analgesic in influenza, but it is probably less effective than phenacetin and salol. Opinions differ somewhat cocerning its value in the treatment of blackwater fever.

It would not be profitable to attempt to discuss the innumerable conditions and diseases in which quinin has been used with reputed success; many of these cases merely serve to illustrate the tendency which the body shows to recover regardless of treatment—even when it is distinctly injurious—and it should hardly be necessary to state that such an active agent as quinin should never be used without having a definite action in view.

Quinin and urea hydrochlorid has been used as a local anesthetic in the same way as cocain.

Quinin is a prophylactic against malaria, and those who are exposed to the bite of the anopheles in malarial regions should take it regularly; but it is of course more sensible to screen houses and destroy mosquitoes than to trust to quinin alone.

DOSAGE

The widest diversity of opinion exists in regard to the dosage of quinin in the prophylaxis and treatment of malaria. Some authorities advise as much as 2.5 gm. (40 grains) daily during the active treatment, and smaller amounts at stated intervals afterward.

A dose of 0.6 gm. (10 grains) of a salt of quinin administered about four hours before the time of an expected paroxysm, and this dose repeated in two hours, will suffice to prevent segmentation and the paroxysm in many cases. When the paroxysm is prevented the administration of quinin should be continued for several weeks. Some advise the administration of doses of 0.3 gm. (5 grains) three times daily for one or two months; others prefer the administration of somewhat larger doses on those days when the paroxysms would fall had they continued, and none on the other days. It seems more logical, however, to use the drug every day. It is especially unfortunate that these questions of dosage have not been determined conclusively, for the continued administration of quinin in large amounts is certainly capable of causing harm in many cases, but the danger of moderate doses for two months is far less than that of an attack of malaria.

---

[1] Guinea-pigs were used in a recent study of the absorption of quinin, but this would appear to be an especially unfortunate choice of animal because rodents absorb certain vegetable poisons from the gastro-intestinal tract very slowly, and apparently not at all, in some cases.

The prophylactic dose of quinin is probably 0.6 gm. (10 grains) daily, preferably taken in two parts.

The tincture of cinchona, or the compound tincture, is generally preferred when the bitter effect is desired; the dose of either is 4 c.c. (1 fluidram) taken just before eating.

MATERIA MEDICA *

The comparative value and uses of the salts of quinin enumerated above are suggested by the following table showing the relative percentage of anhydrous quinin in each and also the relative solubility in water and in alcohol.

	Per Cent. of Anhydrous Quinin	One part soluble in	
		water (parts)	alcohol (parts)
Quinin	85.5	1,750.	0.6
Quinin bisulphate	59.5	8.5	16.
Quinin hydrobromid	76.6	40.	0.7
Quinin hydrochlorid	81.5	18.	0.6
Quinin salicylate	69.9	77.	11.
Quinin sulphate	74.3	720.	86.
Quinin tannate	30.35	800.	3.
Quinin and urea hydrochlorid	60.	1.	....

Quinin and the several salts of quinin may be administered in the form of pills, capsules, cachets, tablets, troches, solutions and mixtures, but the form in which the article is administered should be adapted to the particular salt of quinin used. The solid forms, like pills and capsules, are, of course, adapted to any of the salts of quinin, while solutions of sufficient strength to be active can be made only by the use of the acid salts. Mixtures, on the other hand, are preferably used for the administration of the more or less insoluble alkaloid and tannate. A sirup of glycyrrhiza made by mixing one part of fluidextract of glycyrrhiza with three parts of sirup makes a satisfactory vehicle for any of the slightly soluble salts of quinin. A sirup of yerba santa, which was formerly much used as a vehicle for quinin, is now but seldom employed because it does not compare in elegance or efficiency with the sirup of glycyrrhiza outlined above or a sirup of chocolate, such as is generally used at the soda-water fountain of drug-stores. The commercial form of sweet chocolate is an excellent vehicle for quinin, either in the form of the sirup suggested above or as a simple mixture of quinin tannate or quinin alkaloid with the chocolate in the form of pastilles or troches.

In administering a mixture of quinin it is advisable to direct that the mouth be rinsed with a dilute solution of a weak alkali like sodium bicarbonate, before and after taking the dose of quinin, so as to avoid the bitter taste of a trace of alkaloid which may dissolve in the mouth.

SUBSTITUTES

Among the substitutes which have been proposed for the non-proprietary preparations of quinin are:

Euquinin, which is quinin ethyl carbonate and is claimed to have the same action as quinin with the advantage of being tasteless owing to its insolubility in water and alkaline medium. It is, however, sparingly soluble in water and readily soluble in alcohol and in acid liquids generally, and in solution possesses the characteristic bitter taste of quinin.

Saloquinin, a combination of salicylic acid and the salicylic ester of quinin, which is thought to have the advantage of combining the properties of quinin and of salicylic acid. It is practically insoluble in water but is soluble in acidulated water and moderately soluble in alcohol. Like euquinin, when held in the mouth for an appreciable length of time, it develops a distinct bitter taste and therefore cannot be said to be absolutely tasteless.

These complex salts probably have little or no advantage over quinin alkaloid and quinin tannate, which are much cheaper.

(To be continued)

Therapeutics

PREVENTION IS GREATER THAN CURE

XX

DIPHTHERIA (CONTINUED): PROPHYLAXIS IN SCHOOLS

When it is reported to a school board and to a board of health that a schoolchild is sick with diphtheria, it should first be remembered that with every discovered case probably one other missed case occurs. Of course the sick child is isolated. The other children of this family should have cultures taken from their throats to determine whether or not the Klebs-Loeffler bacillus is present; but without waiting for the results of this investigation, each should receive an immunizing dose of 1,000 units of diphtheria antitoxin, unless their history shows that they are asthmatics or sufferers from hay fever. As it takes from twenty-four to forty-eight hours for the Schick test to develop, it seems unwise, in the case of children who have been in close contact with the infected patient, to postpone the administration of the antitoxin, until a Schick test shows whether or not they are already protected.

These children should, of course, all be forbidden to attend school, and should be isolated as far as possible from other children. If the infected child comes from a tenement house where there are many children, the other children in this tenement should also be excluded from school until it is shown that their throats contain no Klebs-Loeffler bacilli.

If several cases of diphtheria occur one after the other or more or less rapidly in a schoolroom, or in different parts of a school, all of the children who are closely associated, either at their desks, or in classes, or as chums, should have their throats tested to ascertain who are the bacillus carriers. Instruction should be carefully given to the parents of the children who are well but have been positively exposed to diphtheria, to prevent their playing with unexposed children, thus possibly spreading the disease before it is ascertained that they are free from diphtheria bacilli.

General disinfection, by fumigation, of a schoolroom which has contained several diphtheria cases is considered by most advanced sanitary experts as unnecessary and of little value. If swabs from the throats of all the children in this room are taken and the room then closed for twenty-four hours and thoroughly sprayed and washed with germicidal solutions, the other children who do not belong to the infected families may return to the schoolroom as soon as the board of health has determined which throats carry the diphtheria bacilli. It does not seem scientifically wise or economically sensible to close a schoolroom or a school building for an indefinite period when the foregoing measures will be effective in stamping out the disease.

---

* Owing to lack of space the materia medica of quinin has been largely omitted. It will be included when this series is published in book form.

A child whose throat and nose is found to be free from the Klebs-Loeffler bacillus may immediately return to school, provided he is not allowed to come in contact again with a new case of diphtheria. A child whose throat does contain the diphtheria bacilli, though he is not ill, should be isolated and treated with antitoxin if he has been recently exposed, or with the method suggested above for treating carriers, if he has apparently not been recently exposed. Under any circumstances, such a child should not be allowed in school.

The throats of the teachers and instructors in the schools in which diphtheria has occurred should also be tested. Other members of the family in which there is a patient with diphtheria should be examined and if they are found free from the bacilli and do not come in contact with the patient, they can with propriety live at home and attend to their regular occupation. This is on the supposition that the infected patient is properly quarantined (which means the kind of quarantine advised by the board of health), is attended by a physician, and is cared for by a nurse, or by one person who remains isolated with the patient, at least as far as close contact with others is concerned. There is no reason why the nurse should not change her clothing and go out for fresh air daily. She should not go into stores or ride in cars where she might give the disease to others, as she is likely to carry the germ in her own throat, though being herself immune.

TREATMENT

A. Isolation

It should be again urged that a throat with spots or membrane should be considered as likely to be diphtheritic until a culture has proved it not to be. Such a patient should be isolated in the best room available, looking toward the possibility of the disease being diphtheria and a nurse being required. Other children of the family must be excluded from contact with this patient. If the case is clinically one of follicular tonsillitis, the physician may wait for a positive test before giving antitoxin. If, however, the case is clinically diphtheria, antitoxin should be given without a report being waited for, provided there is nothing in the history of the patient to show that there will be any hypersusceptibility to horse serum. If the disease is diphtheria, and the patient is in a tenement where it is impossible to carry out isolation, he should be removed to a contagious disease hospital, if the city has one. Whether it is follicular tonsillitis, or other streptococcic infection, or diphtheria proper, gargles and local cleanliness of the throat should be immediately inaugurated, and when this is properly carried out, the danger of infection of others is reduced to a minimum.

It is hardly necessary in this day, in which the advisability of sunlight, a large room, an adjacent bathroom, the absence of all unnecessary draperies, furnishings, rugs, etc., for a proper isolation room are so well understood, to describe the needs in detail. Instruction should be given the family in the minor details of the prevention of infection of others. A properly trained nurse well understands the necessity for burning wooden tongue depressors, wooden swabs, the gauze and cotton used around the patient's nose and mouth, and washcloths; the use of liquid soap; simple but effective cleanliness of the patient's face, hands, and body; boiling of all eating and drinking utensils; disinfecting the toothbrush with non-poisonous germicides; allowing the bed clothing and bed garments to stand in germicidal solutions before being sent to the wash; frequent washing of her own hands in germicidal solutions; and gargling her own throat with peroxid hydrogen solutions. These are all subjects of general knowledge by physicians and nurses.

B. General Care of Patient

High fever is not frequent in diphtheria, unless the case has been neglected. Consequently, the patient should receive, almost from the beginning, plenty of nutritious food. The exact diet, of course, depends on the age of the patient. The frequency with which the nutriment is given depends on the amount that is taken; if the nourishment is liquid and in small amount, it should be given every three hours. The food should represent all the elements that the patient needs for nutrition, namely, a considerable amount of protein, a goodly amount of starch, sugar, iron, salt and fruit salts, and plenty of water. Milk, oatmeal gruel, eggs, meat juice well salted, toast, butter, and the whole, or the juice, of one or two oranges, would represent the food needed. With or without meat, it is well to give a diphtheria patient iron, and no preparation is better than the tincture of iron chlorid in 5-drop doses, three times a day, given in fresh lemonade or orangeade, after nourishment.

However well the gastric juice inhibits the growth of the bacteria, it is always wise for a patient to gargle, or be sprayed, before taking food, so that the mouth and throat will be as clean as possible.

The bowels should be moved daily by some simple laxative, if they do not move without such help.

While a diphtheria patient should have plenty of fresh air and all the sunlight possible, he should be kept warm. He should not be allowed to become chilled, as the toxins of this disease cause depression and the patient's temperature may be quite low, and the hands and feet easily become cold. Even if the temperature is high, the bathing should be by warm sponge bath.

C. Antitoxin

The Revision Committee of the Pharmacopeia will probably decide that the average dose of diphtheria antitoxin should be stated in the next Pharmacopeia as 10,000 units. Recent investigations by Schick[1] show that the dose of antitoxin advisable for ordinary cases of diphtheria can be based on the weight of the individual. Schick finds that 100 units of antitoxin per kilogram of weight is sufficient to combat the toxin in diphtheria in all ordinary cases, and in severe cases 500 units per kilogram is more than sufficient. In other words, enormous doses of antitoxin are not needed, which has long been the belief of Park of New York. This is especially true if the antitoxin is given early. A kilogram equals 2 1/5 pounds avoirdupois, and a child weighing 45 pounds, in an ordinary case of diphtheria, should be given 2,000 units of antitoxin; while if the case is severe, or in nasopharyngeal or laryngeal types, 10,000 units would be all sufficient. By the same method of decision as to the dose, an adult of about 130 pounds should receive 6,000 units in a mild case, and 30,000 units if the diphtheria is of malignant type, or has affected parts where the danger of absorption is greater.

---

[1] Schick, B.; Kassowitz, K., and Busacchi, P.: Experimentelle Diphtherie Serum-Therapie beim Menschen, Ztschr. f. d. ges. exper. Med., 1914, iv, 83. The Proper Dosage of Diphtheria Antitoxin, editorial, THE JOURNAL A. M. A., Dec. 12, 1914, p. 2134.

It seems quite probable that if such doses could be administered on the first day of the infection with the Klebs-Loeffler bacillus, no more antitoxin will be needed in such cases, and that death from this disease will be reduced to a minimum. It may be wise to give a young child a smaller dose, but it has not been shown, with the concentration of the serums now offered, that locally any harm is done by this injection, or that systemically (except in patients who have received antitoxin in longer or shorter time before, or in patients who are asthmatics or hay fever subjects, or are particularly susceptible to emanations from horses), antitoxin ever does any harm. A slight rash will occur in about half the cases in which antitoxin is used, but such simple eruptions are harmless. The rash may be scarlatiniform in type, or papular, or urticarial. It may occur within a few hours after the injection, or may not occur for some days. If it is in large amount, there may be increased temperature. Mild albuminuria is apparently no more liable to occur from the antitoxin injection than it is from the diphtheria.

The subject of antitoxin injection and dosage has been ably considered by Dr. Woody[2] and by the physicians who discussed his paper. Woody advises that when both tonsils are covered with exudate of more than one day's duration, the smallest dose of antitoxin should be 30,000 units. If both tonsils and the soft palate show membrane, and especially if the nose is involved, and the history shows a duration of three days or more, he would give 150,000 units as the smallest amount. When the nose alone is affected, he believes 20,000 units should be the dose; and in laryngeal diphtheria 30,000 units as the smallest dose is advised. If the case has been a neglected one and there are serious symptoms of toxemia, and especially in nasopharyngeal cases, in which the absorption of toxins is so rapid, he recommends the administration of from 50,000 to 150,000 units. While this dosage seems large, we should note the conclusions offered by Woody after his extensive tabulated experience, namely, that with these large doses there is more rapid local cure and quicker improvement in the patient's general condition, a permanence of the cure, an avoidance of complications, a reduction of mortality, and withal, such dosage is apparently harmless.

Dr. Park of New York, in discussing Woody's paper, advises nearly as large doses, namely, 5,000 units in mild cases, 10,000 in severe, and 20,000 in malignant cases. In toxic cases in which the danger is serious and imminent, he would use the antitoxin intravenously, stating that "10,000 units intravenously is worth 100,000 units subcutaneously." He states his belief that "40,000 units will save any patient that 1,000,000 will."

In a more detailed discussion of diphtheria, Woody[3] brings out some points which we should continually bear in mind. He says: 1. "Diphtheria is essentially a local disease whose harmful effects are produced by certain toxic substances elaborated by the diphtheria bacillus."

2. "The toxin of diphtheria readily reaches all portions of the body by means of the lymphatic circulation." This toxin shows a tendency to attack the kidneys, the nervous system, and the heart. The action of this toxin is inhibited only by the formation of antitoxin in the body, or the introduction of antitoxin into the body.

3. He classifies untoward symptoms following the use of diphtheria antitoxin as: (*a*) Those that occur in eight or ten days after the first injection with symptoms of fever, rash, joint pains, and at times slight albuminuria and edema. In Woody's experience this form of serum sickness occurs in 30 per cent. of the cases of antitoxin injection. (*b*) A similar reaction which may occur after a second dose of antitoxin, provided the source of the antitoxin is the same (that is, the same animal has been used), and which will come on more rapidly and be more intense and last a shorter time. (*c*) Anaphylactic shock or collapse, which he has elsewhere stated to be rare, which may occur after a second injection, and occasionally after the first one.

Smith[4] and Park[5] have shown that when antitoxin is given subcutaneously, it takes from three to four days before the maximum amount of antitoxin is circulating in the blood. If the antitoxin is given intramuscularly this period is shortened. From these findings, therefore, the conclusion should be made that if the case is urgent and the toxemia serious, antitoxin should be administered intravenously; if the case is severe and the diagnosis has not been made early, antitoxin should be given intramuscularly; in ordinary or mild cases, and on the first day or two of the disease, it may be administered subcutaneously.

D. Care of the Throat

It would be just as sensible to perform a major operation with the most perfect technic and yet take no means whatever of preventing infection, as it is to administer antitoxin in proper dose in diphtheria and then to take no proper care of the throat. It should be remembered that diphtheria is primarily a local disease, that the antitoxin combats only the toxins of the Klebs-Loeffler bacillus, that other germs are always found in a diphtheritic throat, and that local putrefaction and septic infection readily occur if the throat and nose are not properly treated. While the antitoxin is hastening the throwing off of the membrane or inhibiting its further formation, the surface of this membrane must be washed off or cleansed gently, but frequently. All odor and all danger of secondary infection are removed by proper treatment of the part affected. Although germicides cannot kill the germs deep in the mucous membrane, or those that are protected by an overlying exudate, a certain large portion of the surface bacteria are surely killed by as simple a gargle as hydrogen peroxid solution. More active and more irritant germicidal gargles or germicides that are sources of danger when swallowed, are entirely unnecessary in diphtheria.

If the child is old enough to gargle or swash the tonsils, this is the best method of cleansing the throat. If the child is not old enough, thorough spraying of the throat should be done. A solution of one part of the official Aqua Hydrogenii Dioxidi to 3 parts of warm water, freshly prepared each time, should be used as a gargle, every one and one-half or two hours during the day, and every three hours during the night. Three or four minutes after this gargle has been used, it should be followed by some simple alkaline wash, to remove the irritant effects of the hydrogen peroxid. A gargle that may be used for this secondary cleansing purpose is a teaspoonful of boric acid added to ½ glass of warm water. This will not all dissolve, but will deposit on the throat and act as a mild antiseptic. Also, there is no greater promotor of mucous secretion of the throat than boric acid; and the more the mucus is secreted, the quicker will the membrane be loosened. Or, a simple solution of ¼ teaspoonful of salt and ¼ teaspoonful of sodium bicarbonate may be added to ½ glass of warm water. The object of such a gargle and wash is to cleanse the mouth and throat of froth and pieces of membrane, mucus, mucopus, etc., and to soothe the membrane. It is frequently advisable to insufflate boric acid directly on the masses of membrane or exudate. This should be done by the physician.

---

[2] Woody, S. S.: The Use of Antitoxin in Diphtheria, The Journal A. M. A., Sept. 5, *1914*, p. *861*.

[3] Woody, S. S.: Pennsylvania Med. Jour., February, 1914, p. 339.

[4] Smith: Jour. Hyg., 1907, vii, 205.

[5] Park: Boston Med. and Surg. Jour., 1913, clxxiii, 73.

After the throat has been cleansed all that is possible, it is often of value to apply tincture of iodin to the membrane or exudate. Care must be taken not to touch the healthy membrane with this solution. Lugol's solution may be applied to the parts of the throat that are not affected, which often tends to prevent development of more exudate or membrane. If there are pockets and crypts in diseased tonsils, after cleansing such, boroglycerid may be applied to heal and to prevent spreading of infection.

As frequent gargling is very tiresome for the throat, swashing is nearly, if not quite, as efficient, and should be suggested. If the child is too young to gargle or swash, the peroxid should be sprayed on, and the solutions for this purpose should be stronger, namely, 1 part to 2 parts of warm water. The cleansing spray may be used afterward. If the throat and mouth generally are irritated, a soothing gargle is as follows:

		Gm. or c.c.	
℞	Acidi borici................	2	gr. xxx
	Potassii chloratis...........	5	ʒ iss
	Aquae menthae piperitae....	200	flʒ vii

M. Sig.: Use undiluted as a gargle, as directed.

Of course, any other flavor than peppermint could be used in this mixture.

Whether or not it is advisable to use a weak hydrogen peroxid solution in nasal diphtheria is a question for individual decision of the physician; generally it is too irritant, even when used weak, and is inadvisable. Cleansing mild alkaline solutions or boric acid solutions represent the most successful treatment of nasal diphtheria used as sprays or snuffed through the nostrils. Such mild, warm solutions may be poured from a small vial or from a teaspoon into the nostril, with the head thrown back. It is inadvisable to use any of the douches that are on the market, or any syphon douche, as the pressure is too great, and fluid is often forced up the eustachian tube or into some of the sinuses. Suprarenal extract may be added to these solutions, if deemed advisable, but it should not be used too frequently. Also, the nose should not be sprayed too frequently.

As soon as the throat is clean, the frequency of the gargles should be diminished, but it should be several days before the patient is not awakened at night to gargle at least once, or better, twice.

The treatment of the throat advised for diphtheria is equally applicable to follicular tonsillitis or scarlatinal throats, and to septic sore throat.

E. General Medication

A diphtheria patient requires very little general medication, unless some complications occur. In the beginning a small dose of calomel, or a dose of castor oil may be advisable, and subsequently whatever simple laxative is needed to cause a daily movement of the bowels. The temperature does not often call for treatment. If it is high, or there is headache and backache and general aches, two or three small doses of a coal-tar antipyretic may be given. The following combination for a child 10 years old is efficient:

		Gm.	
℞	Acetphenetidini	1	āā gr. xv
	Phenylis salicylatis...........	1	

M. et fac chartulas v.
Sig.: A powder every three hours, if needed.

Later, if the temperature is high, tepid sponging is sufficient, but generally, with the ordinary low temperature of diphtheria, hot sponging for cleanliness and to increase the activity of the skin, and to remove the perspiration, should be done once or twice daily.

As suggested above, every patient with diphtheria should receive iron, either the tincture of iron chlorid, a few drops in fresh lemonade, or a 3-grain tablet of eisenzucker, three times a day, or 0.10 gm. (1½ grains) of reduced iron, in capsule, three times a day. If there is a tendency for the throat or nose to bleed, it can do no harm to add lime water to the diet, and it may be of value.

On account of the nervous depression caused by the toxins of the Klebs-Loeffler bacillus, a small dose of strychnin, not exactly as a cardiac stimulant, but more as a nervous stimulant, is advisable, provided the condition of the patient seems to require it. For a child 10 years old, 1/60 grain of strychnin sulphate, once in six hours, is generally a sufficient dose. If the child is made nervous by strychnin, it should certainly be withheld. A little coffee or tea may be given a child, as a medicine for the action of the caffein, and is of value.

(To be continued)

New and Nonofficial Remedies

The following additional articles have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Their acceptance has been based largely on evidence supplied by the manufacturer or his agent and in part on investigation made by or under the direction of the Council. Criticisms and corrections are asked for to aid in the revision of the matter before publication in the book "New and Nonofficial Remedies."

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that, so far as known, it complies with the rules adopted by the Council.

W. A. Puckner, Secretary.

TYPHOID VACCINE (See N. N. R., 1914, p. 259).

Lederle Antitoxin Laboratories, New York City. Schieffelin and Co., New York.)

Typhoid Combined Vaccine (Prophylactic).—Marketed in vials and syringes, each package containing three doses, the first dose containing 500 million killed typhoid bacilli and 250 million killed paratyphoid bacilli A and 250 million killed paratyphoid bacilli B, while the second and third each contain 1,000 million killed typhoid bacilli and 500 million each of killed paratyphoid bacilli A and B.

CANTHARIDIN (See The Journal, Jan. 2, 1915, p. 53).

The following non-proprietary preparation has been accepted:

FAR-REACHING EFFECTS OF LEAD POISONING

To one who contemplates the manifold physiologic activities which are called into progress during the period of gestation in the female, it is not surprising that damage of any sort, whether it be a physical injury or a chemical intoxication, may bring untoward consequences to both the maternal organism and the fetus. The metabolism of the mother is intimately bound up with the nutrition of the young she bears. The transmission of harm, like the communication of disease, follows as a more or less obvious consequence of the intimate connection between the female and her developing offspring. Defective conditions may accordingly affect the embryo independently of any purely hereditary factor. They are, so to speak, the result of a detrimental uterine environment.

The possibility of harm transmitted through the medium of the male is not equally obvious. The germ cell of the male is, of course, the carrier of conspicuous hereditary qualities which manifest themselves in unmistakable fashion in the offspring. This is not equivalent, however, to the contention that damage to the male may deteriorate the germ cell in a way that expresses itself by defective offspring. Nevertheless, the experiments of Stockard[1] on guinea-pigs and of Cole and Davis[2] on rabbits have indicated that alcohol has a deleterious effect on the germ cells of the male.[3]

Lead poisoning in industries in which individuals are exposed to lead in its various forms is reputed to have a detrimental effect on the offspring of the workers, whether male or female. Half a century ago Constantine Paul reported striking observations on the effects of paternal lead-poisoning—cases in which in the course of his work the father was subjected to plumbism, the mother being unaffected. He obtained the history of thirty-two pregnancies of this order; twelve of them resulted in the death of the fetus before term; twenty children were born alive, but the mortality among them was extremely large, only two surviving the third year.[4] Children so born were found particularly liable to various nervous affections. These unusual statistics have not, so far as we are aware, been refuted.

In the department of experimental breeding at the University of Wisconsin, Cole and Bachhuber[5] have clearly shown the effect of lead on the germ cells of the male, in rabbits and fowls, as indicated by their progeny. Their method involved the ingenious device of double mating, which consists in breeding a female of a certain type to two males of unlike type at the same period. In this way the male parentage of the offspring can be recognized by their distinguishing characters. One male was treated with lead, the other remained free from intoxication. It is unnecessary to quote here the actual statistics of these breeding trials. They lead to the conviction that the young produced by male rabbits which have been poisoned by ingestion of lead acetate have a lower vitality and are distinctly smaller in average size than normal offspring of unpoisoned males. In fowls likewise the poisoning of the male parent with lead results in offspring of a distinctly lower average vitality.

The outcome of these investigations furnishes food for reflection. Lead poisoning and the opportunities for it are by no means rarities. There are more than a hundred occupations in which industrial lead poisoning may more or less readily occur, and the cases of known intoxication from such sources reach into the hundreds in some of the larger cities. Plumbism may appear under most peculiar clinical guises and with most unexpected histories. These newly recognized features of the effects transmitted to a second generation complicate its manifestations more than ever.

SANITARY INVESTIGATION OF NAVIGABLE WATERS

The sanitary investigation of navigable waters, authorized by Congress in August, 1912, has been undertaken by the Public Health Service. Three types of waters were selected, the Ohio River, the Potomac River and the coastal waters along the Atlantic and Gulf shores. The watersheds of these present fundamental problems, the solution of which will be of great economic as well as sanitary value. The Ohio River is a source of water supply as well as a means of sewage disposal. The Potomac is a tidal river and is the home of great shell-fish industries. The salt waters of the ocean shores furnish no water supply, but are the receivers of sewage, and the situation of shell-fish beds. The results of the investigations of these fundamental types are expected to serve as a standard in subsequent investigations of a similar nature.

The Ohio River was chosen for the study of the fundamental principles of sewage disposal and the natural processes of self purification of streams. Its length, nearly a thousand miles, and the fact that it has numerous towns and cities along its whole course, make it peculiarly appropriate for such investigation. Cincinnati, Pittsburgh, Wheeling, Portsmouth, Louisville and Paducah were selected as the centers from which to pursue the study, because at these points large amounts of sewage are discharged into the river; at some of them, industrial wastes from coal mines and iron and steel plants complicate the problem, and others are situated on or near the junctions of tributary branches where dilution can be observed. The work embraces the study of the extent, character and population of the watershed of the Ohio, the amount and character of sewage discharged, the effect of the sewage on the river and the river on the sewage, and a complete hydrographic survey of the stream and its various branches. Each substation covers from 15 to 40 miles of the river, and samples of water are collected daily and submitted to bacteriologic, biologic and chemical examination. In this way it is expected to determine the precise point to which the river can be utilized as a means of sewage disposal, while still maintaining the maximum of usefulness to the country bordering it. The sanitary survey of the Ohio River as thus outlined is nearing completion, and the data obtained will soon be available for the use of all concerned.[1]

In the same way, an exhaustive study of the Potomac River has been made, and in addition to the same problems presented by the Ohio there is also the relation of the shell-fish beds to other conditions of the river. When oysters growing in these waters are found to be contaminated with sewage, the problem is whether to remove the oyster beds or treat the sewage discharged in their vicinity. A similar question is involved in a study of the coastal waters of Chesapeake Bay and its estuaries, the gulf and its estuaries, Mississippi Sound, etc.

All the questions involved in the sanitary survey of navigable waters are of immense interest to the public health. Not only is this recognized by the communities most directly affected by rivers and sea coast, but also it is becoming more and more a concern of the whole nation. In this connection it is interesting to note that an extensive study of the boundary waters between the United States and Canada has been made by a joint commission from the two countries. This was authorized by the treaty of Jan. 11, 1909, between the United States and Great Britain, in order to fulfil the agreement of the same treaty, that the boundary waters shall not be polluted on either side to the injury of the health or property on the other.[2]

OILLESS COD LIVER OIL

The experimental study of the alleged nutrient value of so-called cod liver oil cordials, published in this issue by the chemist of the Connecticut Agricultural Experiment Station, Mr. J. P. Street,[1] will serve to expose in an authoritative way the unwarranted claims that have long been suspected by thoughtful students of nutrition. No one will gainsay that cod liver oil, as a natural fat, possesses the energy-yielding attributes of other representatives of this class of foodstuffs. Like other fats, it is readily digested and utilized in the body. There is nothing either unique or remarkable in this behavior. The disagreeable features of cod liver oil, from the point of view of palatability, have as a rule outweighed its availability as a nutrient, not to mention the economic question of the comparative cost of energy obtained in this form. This will help to explain why interested manufacturers have been so eager for many years to retain the reputation of the widely heralded name and at the same time avert these seemingly insuperable objections to the natural oil. The result has been the exploiting of products which are alleged to "represent" the oil, retaining all the virtues without the disagreeable oil itself.

Street's carefully conducted comparative observations under experimental conditions of maintenance and growth, well suited to bring to light the alleged efficiency of a group of widely advertised "oil-free" cod liver oil preparations, leave little to commend the latter. Certainly the alcohol which they contain in quantities up to 18 per cent. cannot be credited with any unusual nutritive or restorative potency; nor is the occasional presence of sugar worthy of peculiar emphasis. Indeed, cod liver oil itself is so far superior to these depleted "extracts" in its contribution to the nutritive functions that the claims of the latter need no longer be seriously considered. Common sense and experiment are in accord on this point.

The fact that a metabolizable fat like cod liver oil is thus clearly superior to the cordials which apparently derive their sole merit from the name which they have appropriated should not lead any one into the other extreme of enthusiasm for the natural product referred to. It is true that recent investigations by Osborne and Mendel[2] have indicated a potency of cod liver oil to promote the growth of certain animals in ways not shared by all of the naturally occurring fats, notably lard, olive oil and almond oil. McCollum and Davis and Osborne and Mendel have likewise found, on the other hand, that this growth-promoting efficiency is common to butter fat and egg yolk fat, either of which are more easily obtained and certainly more readily consumed with relish than is the unpalatable cod liver oil. There seems to be no reason, therefore, for calling on the shelves of the druggist to supply the nutrient virtues which are found in cream and butter and eggs that are a welcomed component of the dietary of persons of all ages. Where cod liver oil might be "indicated," it is quite as rational, certainly cheaper, and admittedly less distasteful to supply these common food products. Above all, let us keep foods and drugs apart; each group has its field of usefulness, but the "combinations" are likely to have no more justification or merit than the extravagant mixtures of antiquated polypharmacy.

POSTANESTHETIC GLYCOSURIA, PURITY OF ETHER, AND DIET

The attention of American physicians has been called somewhat insistently of late to the alleged dangers of traces of certain impurities, notably acetaldehyd, which may occur in ether used for anesthesia; this has been coupled with the advice to use a certain brand claimed to be free of acetaldehyd. The statements as to the supposed harmful effects of these "impurities" have been decidedly indefinite, and no satisfactory evidence has been presented for their correctness.

Recent studies by Ross and Hawk[1] indicate that one result, postanesthetic glycosuria, which may follow the administration of ether and which has been attributed to the presence of "impurities," has nothing whatever to do with these. In a series of experiments on dogs, these investigators found that the administration of ether containing none of the foregoing impurities was followed, other conditions being equal, by the same degree of glycosuria as when one of the ordinarily used brands of ether was employed. There were, however, very marked differences in the manner in which animals reacted to ether, whatever its source; but these differences were found to be due to the character of the food: all dogs which had received a carbohydrate-free diet became glycosuric after ether, whereas none of those receiving a diet containing carbohydrates reacted in this manner.

These experiments show the danger of concluding, because some ethers contain traces of acetaldehyd, and because some patients may have glycosuria after ether, that the acetaldehyd and similar substances are the cause of the latter; experiments show that pure ether will have this effect if the patient is predisposed to it by certain dietary, and perhaps other, habits. Chemists and manufacturers who claim that the U. S. P. tests for the purity of ether are insufficient should present better evidence than they have so far done.

Aside from this aspect of the question, however, the publication of Ross and Hawk is of interest as another illustration of how the factor of diet is often overlooked in the study of the actions of drugs and poisons. In this connection reference may also be made to recent experiments by Opie and Alford,[2] who showed that diet exerts a profound influence on the toxicity of certain substances, namely, chloroform, phosphorus, potassium chromate and uranium nitrate, which cause necrosis of the parenchymatous cells of the liver or of the kidney; the susceptibility to intoxication with all of these substances was less after a diet rich in carbohydrates than after a diet consisting of meat. Of interest in this connection are also the experiments of Hunt,[3] performed some time ago in the Hygienic Laboratory at Washington when, among other results, it was shown that the administration of dextrose diminished the toxicity of acetone for animals.

RADIANT ENERGY AND CATARACTS

The pathologic tissue changes which result in an opacity of the crystalline lens of the eye, in the development of cataract, are still obscure. Beyond the admission that the alterations induced affect the proteins of the parts involved, little of a convincing nature can be said. Obviously one of the fundamental questions concerns the effect of radiant energy on the lens and the humors of the eye. Radiation from a quartz mercury vapor lamp, such as the now familiar Cooper-Hewitt type, can readily be made sufficiently intense to coagulate egg white and solutions of serum proteins and thus render opaque the mediums in which they are dissolved. The effective rays in bringing about this change of state in the proteins lie in the ultraviolet region of the spectrum. An investigation by Dr. Burge[4] at the Nela Research Laboratory has demonstrated that neither the radiant energy from Cooper-Hewitt lamps of 2,400 candle power, or from Mazda nitrogen-filled lamps of illuminating brilliancy, nor the light of the electric furnace or the sun produces comparable coagulating effects on the protein of the normal lens or the vitreous or aqueous humors, provided that the heat effects are properly excluded. A continuous exposure of 100 hours failed to affect the transparency of these structures in the cases investigated under conditions in which egg white was coagulated within an hour.

Here is an apparent anomaly. If radiant energy in the form of short wave lengths is allowed to fall on proteins, it is absorbed and sooner or later the albuminous substances are converted into a coagulated form. Other things being equal, the rapidity with which this change takes place depends on the intensity of the ultraviolet radiation. The fact that the unmodified lens proteins fail to coagulate in the same way under the influence of short wave lengths which readily change the serum proteins, for example, suggests that some as yet unexplained adaptative provision or protective device is present in the complex lens and humors of the eye. Radiations from the infra-red, or the visible regions of the spectrum, cannot coagulate either the modified or the unmodified lens protein, provided the coagulation due to heat be excluded.

[3] Hunt: The Effects of a Restricted Diet and of Various Diets upon the Resistance of Animals to Certain Poisons, Hyg. Lab. Bull. 69, U. S. P. H. S., 1910.

[4] Burge, W. E.: The Effect of Radiant Energy on the Lens and the Humors of the Eye, Am. Jour. Physiol., 1914, xxxvi, 21.

The importance of the chemical character of the solvent mediums of these eye components is made evident by Burge.[4] The lens protein can be modified by solutions of calcium chlorid, magnesium chlorid, sodium silicate or dextrose too weak of themselves to affect the transparency of the lens, so that ultraviolet radiation can precipitate the modified lens protein and hence produce opacity of the lens. Analyses of senile cataractous human lenses show that calcium, magnesium and in lenses from India, silicates are greatly increased in this type of cataract. The assumption is made that the accumulation of these substances modifies the lens protein in such a way that the short waves of the spectrum can precipitate the protein, thus producing the opacity of cataract. The assumption is further made, in the case of diabetic cataract, that the accumulation of sugar in the liquids of the body so modifies the lens protein that the short waves of the spectrum can produce opacity; hence the prevalence of cataract in this disease.

The hypotheses of Burge are, of course, little more than tentative suggestions, in the light of which at least two factors in the genesis of cataract deserve further consideration. One of these concerns the modification of the lens protein by altered nutrition or the incidence of disease; the other relates to the radiation of short wave lengths by which this modified protein can be coagulated. It is an interesting fact, though perhaps little else, that those solutions of salts and organic substances which so alter the lens protein that the short waves can precipitate it, at the same time decrease the fluorescence of the lens. This suggests to Burge that there may be some relation between the latter property and the great resistance of the normal lens protein to ultraviolet radiation.

Current Comment

A CRYSTALLIZABLE URINE PROTEIN

No sooner has the keen observer in these days had his attention directed to some feature of unique pathologic interest than his alertness is rewarded by the discovery of new cases. The Adams-Stokes syndrome, not long since looked on as a novelty, has already ceased to occasion the surprise with which its characteristics were once heralded. The finding of an albuminous substance in the urine comparable in some way with the long-known Bence-Jones protein has ceased to present the rarity of clinical medicine that it did a few years ago. At present the aspects of this proteinuria most discussed relate to the origin of the albuminous substance characteristic of the condition and to the pathologic significance of the urinary product. Recently we discussed some evidence that the food intake is not the decisive causal factor in the origin of the Bence-Jones protein.[1] Most of the cases on record have a history of multiple myeloma, so that this symptom has served to differentiate the disease from other bone lesions. In view of the fact that this text-book statement is likely to stamp Bence-Jones proteinuria with a definite significance for some time to come—as early dogmatic statements in science usually do—it seems worth while to record the occurrence of a new, carefully studied case in the Hamburg-Eppendorf Allgemeines Krankenhaus,[2] in which the existence of myelomatous disease was denied on the authority of a competent pathologist after careful examination of the bone-marrow. This raises the question as to whether there is a diversity of closely related proteins of pathologic import which exhibit the general behavior, in the urine, that is described for the Bence-Jones substance. In reference to this aspect of the subject it may be added that the protein in this newest German case could be separated in crystalline form from the urine. There are a few other instances in the literature of the chemistry of the urine in which crystallization of excreted protein is recorded, notably the spontaneous crystallization first observed by Byron Bramwell and Noël Paton in 1892. Most investigators who have had an opportunity to work with the assumed Bence-Jones protein have not succeeded in obtaining it in that condition of individuality and purity which the crystalline form is commonly believed to guarantee. Failure, however, to crystallize a protein—at best a difficult task—cannot yet be made the basis of diagnostic discriminations. In calling attention to some of the novelties with respect to the Bence-Jones protein we are more than likely to stimulate the discovery of new relationships in reference thereto.

WINTER FLIES

The winter season, naturally, is not the period in which most persons are likely to take measures to prevent the breeding of flies. In the summer, when the flies are thick, the wish will be frequently heard that preventive precautions had been taken. In the course of an inspection, January 7, by the sanitary bureau of New York, in response to complaints regarding a heap of manure, dirt and rubbish not far from a public school in a crowded district of the city, a rather startling state of affairs was revealed. The heap of manure was found partly covered with tar paper and rubbish in which, despite the cold weather prevailing—and there had been not long before a series of days with the temperature well down toward zero—flies were observed to be actively breeding. The *Bulletin*[3] remarks, "This emphasizes the importance of properly caring for horse manure throughout the year and teaches anew why the filthy fly is always with us." Until definite precautions are taken during the winter to prevent the accumulation of heaps of filth and particularly piles of horse manure, in exposed situations under conditions favorable for breeding, the fly will probably continue to be the nuisance and the serious danger to health that it has always been. But it must not be forgotten that whenever we are ready to get rid of the fly nuisance, our boards of health can accomplish this purpose without enormous trouble, probably after the first year without much additional expenditure in the budget, and with little annoyance to the public generally. When it is recalled how much the absence of this undesirable pest would mean for children alone in our crowded city life, it should not be long before there is a general awakening to the necessity of taking the now well-recognized precautions during the winter that will secure great limitation, if not entire obliteration of fly breeding.

THE HEALTH OF OUR SUMMER RESORTS

Many of our summer resorts have acted on the policy that a good climate, charm of location and beauty of scenery are sufficient inducements to attract the summer visitor; but nowadays people are more wary and wisely look for more than this before selecting a vacation playground. The visitor wants a clean bill of health from the resort he has chosen, and is entitled to have one. Vacation typhoid is becoming known as a serious hazard. The prudent recreation seeker now finds out in advance whether or not this infection prevails at the place he has in mind, and furthermore learns what sanitary measures are being taken there to safeguard the health of the summer colony. The town of York, Maine, has recently taken steps that at once place it in the forefront of progress as far as health is concerned. The way the problem was met may well serve as a model for other summer resorts. Last year there were a number of cases of typhoid fever at York. No attempt was made to conceal the fact of the existence of the disease and its extent. The authorities very properly felt that the way to meet any danger was to face it in the open. An expert was invited to come to York and make a sanitary survey. The chief recommendation of the expert was that York needed a full time health officer. The town appropriated $2,500 a year for this purpose and appointed Mr. William Eustis Brown, a graduate of the School for Health Officers of Harvard-Technology, to the newly created position. The town of York is now spending one dollar per capita per year for health, a larger sum than is appropriated by any other American city directly for a like purpose. "Public health is purchasable," the price is moderate, and York shows by its action that it intends to enjoy the best attainable protection from disease. Other summer colonies will find it to their advantage to follow the example of York, and take the necessary measures to safeguard their citizens and the strangers within their gates. People are now advised to demand the security of health that only a well-ordered sanitary department can furnish. Our sea-shore and mountain resorts can no longer depend on nature and luck for a clean bill of health.

RAILWAY ACCIDENTS IN 1914

Accident Bulletin 52 of the Interstate Commerce Commission for the year ended June 30, 1914, shows that there was comparative improvement in the number of accidents on the steam railways of the United States during the year. The total number of casualties for the year was 202,964, of which there were 10,302 killed and 192,662 injured, a decrease compared with the previous year of 662 in the number killed and 7,646 in the number injured. It is to be regretted that the claim of one or two of the larger roads of the country that no passengers were killed on their roads during the year does not apply to all roads, for among the number killed, 265 were passengers. Of the remaining number of killed, 3,259 were employees and 6,778 were other persons classified as trespassers and non-trespassers. It is astonishing to find that doubling the number of employees killed does not quite equal the number killed of persons in no way connected with railroad operation or management or traveling as passengers. It is likewise surprising to note that among the total casualties, 202,964, the killed numbered 409 employees, and the injured 113,274 from "industrial accidents," defined in the Bulletin as "accidents not involved in train operation, but occurring to railway employees, other than trainmen, on railway premises." The total number of employees injured was 165,212, the number of passengers 15,121, and the number of other persons 12,329. While these figures represent a decrease from 1913 of 6,205 injuries to employees, 1,418 to passengers and 23 to other persons, and of 456 employees, 138 passengers and 68 other persons killed, the vast and seemingly unnecessary disproportion between the employees and others killed and injured who have nothing to do with operating or riding on trains undoubtedly calls for further improvement in operating methods, as well as for greatly increased care on the part both of employees and the public to prevent the casualties which are unquestionably the result of individual carelessness.

BLOOD AND RESPIRATION AT MODERATE ALTITUDES

In recent years our knowledge of the conditions pertaining to life at high altitudes has been greatly enriched by careful scientific investigations carried out in various parts of the world, among others at Pike's Peak, Colorado, by the Anglo-American Expedition of 1911.[1] Among other facts brought out is the observation that the pressures of carbon dioxid and of oxygen in the alveolar air decrease progressively with increase of altitude. At any rate, in persons acclimatized at altitudes of 5,000 to 14,000 feet — the latter corresponding to Pike's Peak — the lowering of the carbon dioxid pressure is in direct proportion to the diminution of the barometric pressure. It has been estimated to amount to about 10 per cent. of the sea-level value for each 100 mm. of diminution of the barometric figure. The increase in the red corpuscles of the blood at considerable heights has likewise been commented on in these columns.[2] It has become desirable to obtain supplementary data on the effect exerted at somewhat lower ranges of altitude, below the 5,000-foot level. These have been gathered by Miss FitzGerald,[3] a competent worker in this field of research. The localities chosen were in the Southern Appalachian chain, among the Blue Ridge Mountains in North Carolina, at altitudes ranging from 2,210 to 3,850 feet. The new facts elicited support, or correspond with, those collected at greater heights. In persons acclimatized at these altitudes the partial pressure of carbon dioxid in the air of the lung alveoli is invariably lower than at sea-level, so that the lung ventilation is correspondingly increased. As at higher altitudes, the percentage of hemoglobin in the blood is increased, in accord with the previously published view that for every 100 mm. fall of atmospheric pressure the percentage of hemoglobin is augmented by about 10 per cent. of the normal value for men at sea level. The same features apply to women, though greater irregularity obtains in connection with the observations on them.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

ARKANSAS

Sanatorium Incorporated.—The Ozark Sanatorium has been incorporated at Hot Springs with a capital stock of $75,000 by Drs. Thomas E. Holland, William V. Laws and William T. Wootton.

Hospital Notes.—The mayor of Little Rock urges the erection of a city hospital at a cost of $150,000, the funds for same to be secured by a bond issue. He also suggests that the institution shall retain the name Logan H. Roots Memorial Hospital.—The Quorum Court of the Fort Smith District has appropriated $2,000 toward the erection of a detention hospital in the city of Fort Smith. The building will be located on the grounds of the Sebastian County Hospital.——The dean of the medical department of the University of Arkansas recommends the establishment of a state hospital in connection with the department which will make possible the advancement of the college to the class "A" rank. The proposed location for the hospital is in the rear of the old State House.

ILLINOIS

New Medical Society.—The Freeport Academy of Medicine and Surgery was organized, February 5, with an initial membership of 18 and the following officers were elected: president, Dr. William B. Peck; vice-president, Dr. Dupuytren L. Mease; secretary, Dr. Theophil J. Holke; treasurer, Dr. Edgar J. Torey.

Scarlet Fever at Decatur.—February 6, Decatur was placed under general quarantine by the State Board of Health on account of an epidemic of scarlet fever. It was reported that there were about 100 cases in the city and regulations were adopted as to visiting public places, violating quarantine rules, etc.

State Civil Service Examination for Food Bacteriologist.—On April 3 an examination will be held at Anna, Carbondale, Chicago, Dunning, East St. Louis, Elgin, Jacksonville, Kankakee, Lincoln, Macomb, Mt. Vernon, Peoria, Pontiac, Springfield, Urbana and Watertown to provide an eligible list for the position of food bacteriologist in the Chicago office of the State Food Commission. The salary at present is fixed by law at $1,800 a year. The limits recommended by the State Civil Service Commission are $150 to $175 a month. The examination will be open to non-residents, as well as residents, of Illinois over 25 years of age.

The duties of the position involve making bacteriological examinations (and interpreting the results of such examinations) of milk, ice cream, eggs, meat, tomato products, etc., in accordance with the dairy, food and sanitary laws.

Chicago

Personal.—Dr. Norman H. Weston dislocated his right wrist and ankle in the Central Y. M. C. A. Gymnasium, February 10.——Dr. Edward B. Weston, for many years secretary-treasurer of the National Archery Association of the United States, has resigned on account of impaired health.

Opening of the Municipal Sanatorium.—Unique in public institutions is the Chicago Municipal Tuberculosis Sanatorium which was dedicated February 16, in that at the time of the dedicatory exercises, the buildings were ready for occupancy; the heat, light, power and refrigerating plants in operation; the roads and paths laid out; the bulbs set out, shrubs and grass planted; meat was in the refrigerators, the bakery was in operation, food and other supplies were in place, beds made, and porch klondikes and summer sleeping kits all ready for use. To-day the sanatorium could take in 500 or more patients and care for them as well as if the institution had been in operation for ten years. The dedicatory exercises were attended by about 2,000 people and this, considering the distance from the city and the coldness of the day, is a marked evidence of the general public interest taken in this life-saving project. After prayer by Father Peter J. O'Callaghan, Dr. Theodore B. Sachs, president of the board of directors, gave a short address chiefly historical in character, and presented the gold master-key with key ring and tag suitably inscribed to Health Commissioner Dr. George B. Young, who accepted the key on behalf of the mayor who was unable to be present on account of illness. Senator Glackin who made the sanatorium possible by introducing the bill in the legislature, and Director W. A. Wieboldt also made addresses. At the conclusion of the dedicatory ceremonies, nurses were in attendance and conducted the guests through the institution. All buildings excepting the gate lodge, superintendent's house, garage and farm buildings are ready, and these are from one-half to two-thirds completed. The opening of the institution for patients will be delayed for about ten days that the staff personnel may be completed. Sites have been selected, plans prepared, and sewer, water and heat connections prepared for cottages for 300 additional patients and these buildings will be erected as soon as the necessity arises. Dr. J. W. Coon, formerly superintendent of the Wisconsin State Sanatorium, Wales, is superintendent and the greater part of the professional and lay staff has already reported for duty.

INDIANA

Personal.—Dr. Lewis C. Griffith, Bowling Green, who was charged with setting fire to his drug store, was found not guilty by a jury in Clay Circuit Court, February 12.——Dr. Emma Martin of Otterbein sailed February 5 for Peking, China, where she will become superintendent of a new missionary hospital under the auspices of the Methodist Episcopal Church.

Child Welfare Exposition.—A child welfare exposition is being held at Tomlinson Hall, Indianapolis, February 16 to 25. Many of the state departments and many health associations are participating, as it has the active support of both the state and the city board of health. The reason for this exposition is to show that prevention is better than cure. Model rest rooms, nurseries, kindergartens, summer missions and child's libraries are in operation, together with demonstrations in domestic science and of ideal school rooms.

---

[2] Altitude and Blood-Corpuscles, editorial, The Journal A. M. A., Feb. 3, 1912, p. 344; Physiologic Features of High Altitudes, Sept. 21, 1912, p. 942; The Blood Phenomena of Altitude, July 26, 1913, p. 283; The Influence of Altitude on the Blood, Nov. 1, 1914, p. 1634.

[3] FitzGerald, Mabel P.: Further Observations on the Changes in the Breathing and the Blood at Various High Altitudes, Proc. Roy. Soc. (B), 1914, lxxxviii, 248.

Legislative Action.—All bills before the state legislature in regard to health officers have been indefinitely postponed. ——The pharmacy bill which was intended to raise the standard of pharmacy in the state has also been killed.——The eugenic bill has been changed to apply to both men and women by the house and as the senate struck out the feature applying to women, it will also probably be killed.——The bill establishing an examining and licensing board of chiropractors has been amended to such an extent that it would require three years of nine months each of attendance at a chiropractic school and also place the head of the department of anatomy at Indiana University and the head of the department of physiology of Purdue University on the examining board.

IOWA

Health Survey of Cities Planned.—The State Board of Health intends to abandon the method of requiring periodical chemical and bacteriologic examination of water supplies in favor of the more scientific method of surveys under the direction of a civil and sanitary engineer of the State Board of Health, who has been working along this line since the reorganization of the board.

Personal.—Drs. Edward T. Alford and William H. Bickley, Waterloo, have opened a clinical laboratory in Waterloo under the charge of Dr. Ivey, formerly of Mobile, Ala.—— Dr. G. Walter Barr, for nearly a quarter of a century a resident of Keokuk and for eight years secretary and executive officer of the Keokuk Medical College, has been appointed efficiency engineer on the staff of the president of Highland Park College, Des Moines.

Small-Pox in Chiropractic School.—The discovery of a case of small-pox in a student in the Palmer School of Chiropractic, Davenport, has led to the threat by city physician, Dr. George M. Middleton, Davenport, to close the school to all pupils who refuse to be vaccinated. The chiropractic method of treatment and prevention will not be recognized. The neighboring city of Rock Island, Ill., also reports a number of cases of the disease.

MARYLAND

Sanatorium for Negroes.—The city health officer of Cumberland has recommended the establishment of a sanatorium on Haystack Mountain for the care of negroes afflicted with tuberculosis.

Personal.—Dr. William Lee Smith, Riderwood, who has been confined to his bed for the past three weeks, is slowly improving.——Dr. Newell A. Christensen, in charge of the accident ward of the Mercy Hospital, Baltimore, has resigned.

To Improve Bay View Asylum.—The Board of Estimates of Baltimore city has given authority to Dr. J. Hall Pleasants, Jr., Baltimore, president of the supervisors of city charities to spend about $10,000 in improvements at Bay View Asylum. It is proposed practically to rebuild the tuberculous ward at a cost of $5,000.

Warns Against Bubonic Plague.—That Baltimore is gambling with the health of the people and the commerce of the port against the probability of an epidemic of the bubonic plague and that preventive measures ought to be taken to prevent a development of the plague here was stated by Dr. William C. Rucker, Washington, D. C., of the U. S. Public Health Service, in an address before the Public Health Conference, recently held in Baltimore. He made it plain that every municipality that failed to take preventive measures is likely to find itself in the position of New Orleans, where the government, state and city authorities were spending hundreds of thousands of dollars to wipe out the bubonic plague, which might have been prevented, had there been a rodent survey of the city. The federal government has been willing to cooperate with the city authorities of Baltimore in making a rodent survey, but the city has refused to appropriate any money for such a purpose, although Health Commissioner Gorter has asked for such an appropriation.

MICHIGAN

Personal.—Dr. Eugene Grignon, Menominee, is ill in St. Joseph's Hospital, Marinette, as the result of a cerebral hemorrhage, January 31.——Drs. Collins H. Johnston and Ralph C. Apted have been elected directors of the Grand Rapids Antituberculosis Society.

Believes in Public Meetings.—Dr. Edward T. Abrams, Hancock, a member of the State Board of Health, recently advocated that the public be asked to attend the meeting of the Houghton County Medical Society, at which three papers were to be read on small-pox and vaccination. This he felt would be a good means of giving the public a better understanding of the importance and value of vaccination in the prevention of threatened epidemic small-pox in northern Michigan.

Small-Pox in the Upper Peninsula.—Small-pox exists in nearly every copper country town and in many of the iron country towns. The outbreak at Crystal Falls is said to be the worst in the history of the upper peninsula, although the disease itself is present as yet only in a mild form. There have been no deaths. Dr. Joseph A. Crowell, Iron Mountain, has been appointed a special agent of the State Board of Health to investigate the situation in that vicinity.

MINNESOTA

Personal.—Dr. William G. Crumley, Rochester, has been appointed consulting intern in the American Hospital, Paignton, Devonshire, England.——At the annual meeting of the Antituberculosis League of Olmsted County held in Rochester, January 13, Dr. Charles H. Mayo was elected president and Dr. Walter DeW. Shelden, vice-president.

No Leper Colony for Minnesota.—Dr. Henry M. Bracken, St. Paul, secretary and executive officer of the State Board of Health, calls attention to an item in The Journal of January 23, and states that there are now only eight known lepers in the state, and three of whom no trace can be obtained. Of these eight cases, five patients are living at home and not endangering the people in their community or in their own homes, and are under proper care and treatment. The other three patients are dependents and are being cared for by their respective counties. Dr. Bracken approves a federal leprosarium, but considers the plan exploited in the lay press and mentioned in The Journal as an absurdity.

Antituberculosis Plans.—Dr. Robinson Bosworth, St. Paul, announces that the advisory commission of the State Sanatorium for Tuberculosis will ask for an appropriation of $750,000 for county sanatoriums.——At a meeting of representatives from Blue Earth, Nicollet, Brown, Watonwan, Faribault, Waseca and LeSueur counties held at Mankato, January 30, a joint sanatorium to cost $150,000 was suggested.——Yellow Medicine, Lac Qui Parle, Chippewa and Renville counties have arranged for the establishment of a sanatorium to cost $60,000.——Grant, Stevens, Douglas and Polk counties are to have a joint sanatorium to cost $60,000. ——Plans are being made for a joint sanatorium at Austin, for Steele, Dodge, Freeborn and Mower counties.——The State Advisory Commission is endeavoring to arouse public sentiment in Carleton that it may cooperate with Pine, Kanabec and Isanti counties in the establishment of a joint sanatorium.——It is also hoped that Kitson County will cooperate with Marshall and Roseau counties in plans for tri-county sanatorium.

Mayos Give Million for Research.—After long consideration the Drs. William J. and Charles H. Mayo have recently consummated their plans for the endowment of the graduate medical instruction and research work which has for years been a feature of the Mayo Clinic at Rochester, Minn. The result is the incorporation of "The Mayo Foundation for Medical Education and Research, Incorporated," with an initial endowment fund of $1,500,000. The founders are: William J. Mayo, Charles H. Mayo, Henry S. Plummer, Edward Starr Judd and Donald C. Balfour. The board of temporary trustees having in charge for the present the investment of the fund is composed of Bert W. Eaton, George W. Granger and Harry J. Harwick. The board of scientific directors is composed of Louis B. Wilson, William F. Braasch, E. Hessel Beckman, A. H. Sanford and Walter D. Sheldon. For the present the expenses of the foundation will be met by annual contributions from the Mayo Clinic, the income from the endowment being allowed to accumulate and increase the principal.

MONTANA

Personal.—Dr. Thomas D. Tuttle, Warm Springs, superintendent of the Tuberculosis Sanatorium, Galen, has resigned to accept the position of commissioner of public health of the State of Washington.

Surveyor-General Suggests Changes for State Health Board.—The surveyor-general of Montana is said to have nounced his intention of suggesting changes in the personel of the State Board of Health. These changes provide hat the board be made up of the governor, the attorney-general, the state veterinarian, one practicing physician, one chemist with a knowledge of bacteriology, one civil engineer with experience in municipal engineering and one dairyman.

NEW JERSEY

Medical Club Organized.—A medical club, to be known as the Aesculapian Club, recently has been organized among the younger practitioners of Jersey City, with twelve charter members, and the following officers have been elected: president, Dr. Charles B. P. Kelley; vice-president, Dr. George H. Mueller, and secretary-treasurer, Dr. David L. Russell.

Hospital Opened at Riverside.—The Zurbugg Memorial Hospital, a monument to the late T. Zurbugg, for years head of the Keystone Watch Company at Riverside, who left $250,000 to establish the institution, was officially opened by Mrs. Zurbugg with the handing of the keys to Dr. Alexander H. Small, Riverside, chief surgeon. February 12 Mrs. Zurbugg announced that the present quarters represent only the beginning of the work planned by her husband. The hospital in the remodeled mansion of the Zurbugg's will later be converted into a nurses home when a new hospital capable of caring for the sick of Burlington County, will be erected on grounds adjoining.

NEW YORK

Gift to the University of Buffalo.—Property valued at $125,000 has been given to the University of Buffalo by the Woman's Educational and Industrial Union, to be used as a coeducational college of liberal arts and sciences and on condition that within one year the university will raise $100,000 for endowment and that three free scholarships for women be maintained annually in the College of Liberal Arts and Sciences.

Personal.—Dr. John Van Duyn, Syracuse, celebrated the fiftieth anniversary of his entry into practice, February 5. On February 23, Dr. Van Duyn is to be the guest of honor at a banquet given by the Onondaga County Medical Association.——Dr. J. Wilson Poucher, surgeon in chief of St. Francis' Hospital, Poughkeepsie, gave a buffet luncheon recently to twenty-six members of the medical and surgical staff of the institution.——Dr. Albert Vander Veer of Albany has been chosen for regent of the University of the State of New York to succeed himself by unanimous vote in both houses of the legislature. The term is for twelve years.

Antivaccination Measure.—The Jones-Tallett bill which opposes the compulsory vaccination of schoolchildren except when there is an epidemic of small-pox in the locality of the school has been up for hearing. It is reported that Health Commissioner Hermann M. Biggs, New York City, and other officials favored the measure while many physicians from all parts of the state came to Albany to oppose its passage. Among those opposing the bill were Dr. Lewis K. Neff, New York City, chairman of the legislative committee of the State Medical Society; Dr. William J. Cruikshank, Brooklyn, representing the Kings County Medical Society; Dr. Abraham Jacobi, New York City, and Dr. Franklin C. Gram, Buffalo.

Civil Service Examinations.—The New York State Civil Service Commission announces that an open competitive examination will be held in various cities throughout the state February 27, for Director, Division of Communicable Diseases, salary $4,000; open to men only, physicians of not less than five years' standing and not more than 60 years of age; and for Director, Division of Public Health Nurses, salary $2,500; open to women only, physicians or registered nurses. All competitors must execute application blanks and file them with the commission on or before February 23. The examinations are open to residents and non-residents without restriction, but all candidates must be full citizens of the United States.——It is announced that twenty applications have been received for the position of superintendent of the new Onondaga County Tuberculosis Hospital, for which a civil service examination is to be held, February 27. The position is open to male physicians, licensed to practice in the state and the salary is $2,500 and maintenance for the superintendent and his family.

Semicentennial of Health Department.—At the February meeting of the New York Academy of Medicine, the program of which was arranged by the board of health, Dr. S. S. Goldwater presented a letter to the council of the academy stating that "For some time health authorities have been much concerned regarding the definite increase in the mortality of the higher age groups, an increase manifesting itself particularly in certain degenerative diseases like arteriosclerosis, Bright's disease, cirrhosis of the liver, apoplexy and certain malignant diseases like cancer. Much has been accomplished in recent years in saving infant lives, but it seems difficult to arouse people, or even the medical profession to the surpassing importance of instituting hygienic measures for persons in adult life. Dr. Charles F. Bolduan, director of the Bureau of Public Health Education, has been conferring with a number of prominent health authorities and suggests that something spectacular is needed to initiate a campaign to combat this increased mortality. Plans have therefore been discussed for holding an exhibiiton of adult hygiene in this city in 1916, the fiftieth anniversary of the organization of the department of health. The dignity and effectiveness of this exhibit will be increased if it is held under the auspices of the Department of Health of the City of New York, the Department of Health of the State of New York and the New York Academy of Medicine and the American Museum of Natural History. The council of the academy recommended that the academy approve of this scheme and take part in this exhibit.

New York City

Personal.—Dr. Ernest Everett Just was presented with a gold medal at the annual meeting of the National Association for the Advancement of Colored People by Governor Whitman for special research work in physiology and zoology.——Dr. Thomas W. Carey has resigned his position on the staff of the Willard Parker Hospital and has gone to Washington, D. C.

Plan Million Dollar Hospital.—At the annual meeting of the Beth Israel Hospital Association, February 11, it was announced that a new hospital building is planned to be erected on Livingston Place. It will be twelve to fifteen stories in height and accommodate 500 patients. A special feature of the hospital will be the accommodations for persons of moderate means who do not wish to be charity patients and yet are unable to pay high charges for services and attendance.

NORTH CAROLINA

Salisbury Recommended for State School.—The special legislative committee of the 1913 assembly filed its report, January 26, recommending the removal of the State School for the Blind, from Raleigh to Salisbury.

Personal.—Dr. George W. Shipp, Newton, has been elected physician for Catawba County.——Dr. Chalmers M. Van Poole, Salisbury, who has been seriously ill at his home for several weeks with ptomain poisoning, is reported to be convalescent.

OHIO

New Health Department Laboratory.—The laboratory committee of the Hamilton Board of Health has rented a building for laboratory and headquarter purposes, and has equipped the laboratory at a cost of nearly $1,000.

Personal.—Dr. Jacob A. Kimmell, Findlay, was elected chairman and Dr. Cornelia B. Kennedy, Findlay, secretary, of the Findlay Branch of the Federation of Medical Societies for the Public Health.——Dr. George W. Crile, Cleveland, who has been abroad in connection with the American Ambulance Hospital, Paris, sailed on February 13 for America.

Five-County Hospital Opened.—The Springfield Lake Tuberculosis Sanatorium, jointly established by Summit, Portage, Mahoning, Stark and Columbiana counties, at a cost of nearly $250,000, was opened February 1. The institution has accommodations for seventy-two patients and this can be doubled in case of necessity. Dr. Stanton K. Crawford, Lakewood, has been appointed superintendent of the institution.

Public Health Conference at Columbus.—On January 28 and 29, the forty-first conference of the Ohio State Department of Health, with representatives of local boards of health, was held at Columbus. This conference was for representatives of cities only. The conference was addressed by Governor Willis on the subject of health conservation. Dr. John R. McDowell, Zanesville, spoke of the health department under the commission-manager form of municipal government. The danger of polluting a public water supply by industrial connections was discussed by Mr. L. H. Van Buskirk of the State Department. He mentioned several epidemics of typhoid fever as a result of this practice in Ohio. Dr. E. R. Hayhurst, Columbus, gave a summary of the results of the Ohio Survey of Industrial Hygiene and Occupational Diseases, while Dr. E. F. McCampbell, secretary and executive officer of the State Department, discussed the contemplated work of the Ohio Public Health Federation and the public health legislation introduced into the present general assembly.

Columbus Academy Banquet.—On February 1 a complimentary dinner was tendered by the Columbus Academy of Medicine to its members. All members of the general assembly who are physicians were guests. Dr. John H. J. Upham, president of the Ohio State Medical Association, spoke of the need for unity and organization if quackery were to be vanquished and the medical profession maintain its present elevated position. Judge Wanamaker of the supreme court of Ohio addressed the members on the relation of the law to medicine. President Thompson of Ohio State University emphasized the necessity of maintaining high standards of medical education; complimented the American Medical Association on the part it had played in the past, and foresaw that the medical school must set the ideals for the profession in the future or fail in its purpose. Representative Carl D. Hoy, M.D., Columbus, spoke of the necessity of purging the profession of the fee-splitting evil, and mentioned a bill he had recently introduced with that purpose in view.

Proposed Legislation Affecting Public Health.—Among the bills introduced into the general assembly affecting the public health are two very important measures, one, directing the Ohio State Board of Health to manufacture diphtheria antitoxin and distribute it free to indigents in Ohio by means of various distributing stations, and another, to transfer the Bureau of Vital Statistics to the Ohio State Board of Health. This last measure has been approved by Dr. C. V. Chapin, health officer of Providence, R. I., and many eminent statisticians and public health workers throughout the country. The bill for the manufacture and free distribution of antitoxin has been introduced in several previous legislatures, but has always failed of passage. At present there is a working agreement with one of the large antitoxin houses to supply antitoxin to boards of health at reduced prices, but this arrangement is not completely satisfactory.——During this session of the general assembly it is also hoped to effect the passage of a bill transferring the food and drug work of the Agricultural Commission to the laboratories of the Ohio State Board of Health.

PENNSYLVANIA

Personal.—Dr. George W. Guthrie, Wilkes-Barre, who has been ill for the past six months, suffering from pleurisy, is reported convalescent and expects shortly to go to Atlantic City to hasten and complete his recovery.——Dr. W. Knowles Evans, commissioner of health of Chester, is said to be seriously ill with pneumonia.

Mellon Lecture.—Prof. John J. Abel, Johns Hopkins University, will deliver the Mellon lecture under the auspices of the Society for Biological Research of the University of Pittsburgh, at the Mellon Institute for Industrial Research, February 27, on "Experimental and Chemical Studies of the Blood and Their Bearing on Medicine." This lectureship has been endowed by Mr. Richard Beatty Mellon, Pittsburgh.

Philadelphia

Personals.—Dr. F. X. Dercum has been appointed consulting physician of the medical staff of the State Hospital for the Criminal Insane at Fairview, Wayne County.——Prof. C. Wardell Stiles of the Rockefeller Hookworm Commission delivered the ninth Weir Mitchell lecture of the College of Physicians, February 16.

West Philadelphia Stock Yards Closed.—On February 12 the West Philadelphia Stock Yards were placed under complete quarantine by Dr. Charles Schauffler of the United States Bureau of Animal Industry, and a thorough cleansing and disinfecting of the yards ordered. A consignment of cattle recently shipped here was discovered to be infected with foot-and-mouth disease.

Evans Museum to be Dedicated.—The Thomas W. Evans Museum and Dental Institute of the School of Dentistry of the University of Pennsylvania, Philadelphia, will be dedicated and opened for inspection, February 22 and 23. On the first day, the formal dedication exercises will be held with addresses by Dr. Charles Godon, Paris, France; Prof. Dr. Wilhelm Dieck, Berlin, Germany; Mr. John Howard Mummey, M.R.C.S., L.D.S. London, England; Dr. William Simon, Baltimore, and Dr. Edward Kirk, dean of the Evans Museum and Institute; presentation of key by the architect, Mr. John T. Windrim; acceptance on behalf of the Thomas W. Evans Museum and Institute Society by the president, Hon. John Weaver, and on behalf of the trustees of the University, by Dr. Edward F. Smith, provost of the University of Pennsylvania, and the conferring of the degrees by the provost. After the exercises the building will be open for inspection. On the second day the buildings will be open for inspection, exhibits of various subjects in science and education will be shown and sixty-seven clinics will be held to which the alumni and practitioners are cordially invited. The building is one of the largest on the campus and has been erected at a cost of nearly $1,000,000, as the gift of the late Dr. Thomas W. Evans, philanthropist and dentist, who practiced for many years in Paris and died in 1897.

TENNESSEE

Tributes to Surgical Dean.—At a meeting of the Shelby County Medical Association, February 2, eloquent tributes to the memory of the late Dr. William B. Rogers, Memphis, setting forth his excellences as a physician, citizen and a friend, were paid by members of the society.

Fear of Chattanooga Situation Unwarranted.—Dr. Richard H. Creel, San Juan, P. R., surgeon, United States Public Health Service, has reported to Surgeon-General Rupert Blue, Washington, D.C., that a thorough investigation shows no evidence of plague and that the situation as regards small-pox is not alarming. The total number of cases up to the date of the report, January 15, was fifty-six, with sixteen deaths. Dr. Creel reports that vaccination is extensively employed and prohibitive quarantines by neighboring towns are unjustifiable. He says that demand for evidence of successful vaccination in the traveling public from Chattanooga would not be burdensome and would meet all necessary requirements.

Vaccination in Knoxville.—The presence of virulent small-pox at Chattanooga during the fall and winter has prompted the health authorities more rigidly to enforce the vaccination ordinance, and the director of the department of health, Dr. William R. Cochrane, Knoxville, has issued an order requiring all school children in Knoxville, who cannot show a recent scar, to be vaccinated immediately. The director also urges all other persons to avail themselves of the protection afforded by vaccination. Officials of Chattanooga have invited a committee of the Knoxville Board of Commerce to visit the former city, where the small-pox situation is now well in hand. More than fifty thousand vaccinations were made in Chattanooga on account of the epidemic there. No quarantine is contemplated against Chattanooga by Knoxville.

TEXAS

Medical Staff Resigns.—Thirty-six of the forty-two members of the medical staff of St. Paul's Sanitarium, Dallas, resigned recently for reasons which they declined to disclose.

Health Officers Qualify.—Dr. William B. Collins velady, qualified as state health officer, January 28.——D illiam A. Davis, Jr., Jourdanton, registrar of vital st and secretary of the State Board of Health, qualified ame day.

Society Seeks Headquarters.—The Bexar Cou al Society has negotiated with the Central Trust C n Antonio, for the lease of five or six floors in al Trust Company's new building. The plan is to n auditorium for meetings, a library, reading room rooms, and also to rent space for offices to mem society.

New State Board Officers.—At a joint session of new state boards of medical examiners held in ruary 3, the old board adjourned sine die and the perfected organization with the following officers: Dr. Thomas J. Crowe, Dallas; vice-president, Dr. Bettencourt, Fort Worth; secretary-treasurer, Dr. McElhannon, Belton.

CANADA

National Sanatorium Offices Formally Opened.—O ary 10 the lieutenant- formally opened general offices of the N atorium Associati lege Street, Toronto. T rection of this b Mr. W. J. Gage, Toronto, 100,000. Mr. G also donated $10,000 towar rships in co with research work in tuberculosis. Since the first sanatorium was established in Gravenhurst, some sixteen years ago, the deaths in Ontario have decreased from 2,800 annually to a little over 2,000.

Personals.—Dr. James Roberts, medical officer of health, Hamilton, Ont., has been granted leave of absence, to proceed to the front with the Second Stationary Field Hospital as captain. Dr. Major H. Langs will be acting medical officer during Dr. Roberts' absence.——Dr. Howard Burnham, son of Dr. George H. Burnham, Toronto, has been sent in charge of a British Red Cross party to Montenegro. Previous to the commencement of the war Dr. Burnham was a house surgeon at the Toronto General Hospital.——Dr. Hugh A. Stevenson has been elected mayor of London, Ont.——Dr. William J. Charlton, who was recently elected the first mayor of Weston, Ont., has had his election successfully protested by his opponent, Dr. Eli F. Irwin.

University News.—Medical students from the University of Toronto will largely compose the staff of the Clearing Hospital which will accompany the Second Canadian Contingent to France. Between forty and fifty fifth-year medical students will be taken following a request for volunteers. They will be given credit for their year on enlisting. The organization of the unit is in charge of Dr. George S. Rennie, Hamilton, Ont. When it arrives in France it will be in charge of Dr. Wallace A. Scott, Toronto, who went with the first contingent. Accompanying it will be Dr. George S. Strathy and Dr. L. Bruce Robertson, Toronto, and Drs. Foster and James E. Davey, Hamilton.——Dr. H. B. Yates, Montreal, is to be second in command to Dean Herbert S. Birkett of the medical faculty of McGill University of the McGill University General Hospital, which is to go to France. The other officers who are to be appointed to the various ranks are: Drs. John M. Elder, John McCrae, J. George Adami, W. Henry P. Hill, Edward W. Archibald, A. Howard Pirie, L. J. Rhea, William G. Turner, C. P. Howard, Herbert M. Little, William B. Howell, Colin K. Russel, John W. Hutchinson, John C. Meakins, William W. Francis, J. A. MacMillan, R. H. M. Malone, Laurie H. McKim, and Mr. David Law, all of Montreal. Numerous subscriptions for the equipment of this hospital have been received by Dr. Herbert L. Birkett, among others being one from Dr. and Mrs. Casey A. Wood, Chicago.

GENERAL

Coastguard Hospital Ship.—The United States coastguard cutter, *Androscoggin*, returned to port February 1, and reported that during her last month's cruise she had given aid in one case of appendicitis and in one case of serious eye disease.

Lake Water to Be Boiled.—Secretary McAdoo issued an order February 9, prohibiting vessels on the Great Lakes and rivers from serving to their passengers water from the lake or stream over which the vessel is being navigated, unless the purity of the water has been assured. This order is the result of an investigation by the U. S. Public Health Service due to typhoid epidemics resulting from lake travel.

Congress Organized.—The American Congress of Internal Medicine was incorporated at Albany, February 2, with the object of facilitating scientific investigations by physicians interested in internal medicine and for the promotion of good fellowship. The incorporators are Drs. Reynold Webb Wilcox, Heinrich Stern, Louis Faugeres Bishop, D. Morvay Rottenberg and Thomas F. Reilly, all of New York City.

Medical Students in English Universities.—The General Council on Medical Education of Great Britain has issued an announcement showing that the total enrolment of medical students throughout the United Kingdom has been reduced by about 1,000. It is estimated that the number of those added to the profession this year will be from 200 to 300 less than the average, which means a diminution of about 25 per cent. The number of physicians annually removed from the Register for several years past has been about 800, and it is anticipated that additional losses will result from the war. The large reduction in the enrolment in medical schools, therefore, is viewed with grave concern.

More Warnings.—Dr. Walter H. O'Neal, Gettysburg, writes that a young man who goes by the name of M. E. Bergendahl of Hagerstown, Md., has been canvassing the physicians of Gettysburg, soliciting subscriptions for the *Keystone Circulating Magazine* of Philadelphia, and stating that he was endeavoring to secure a sholarship in the University of Maryland Medical School, and that each subscription received entitled him to a certain number of votes. The magazine company says that this man is a fraud and not authorized to receive subscriptions.——The Order of Owls offers a reward of $100 for the arrest and conviction of J. C. Gavil, purporting to be an organizer for the order. This man is said also to go by the name of J. O. Gamble. He has been operating in Arkansas.

Bequests and Donations.—The following bequests and donations have recently been announced:

Children's Hospital, Philadelphia, a contingent bequest of $28,000, after the death of a brother and sister, by the will of Robert Johnston.

Peter Bent Brigham Hospital, Boston, $50,000; Sheran, Mass., Sanatorium for Consumptives; Childrens Island Sanatorium; Noble Hospital, Westfield, Mass., each $1,000 by the will of Mrs. Ellen R. Goldtwaithe.

Children's Hospital, Boston, $5,000 by the will of James C. Melvin, Carlisle.

Free Hospital for Poor Consumptives, Philadelphia, $7,000 by the will of Thomas McCartney.

Germantown Hospital, Philadelphia, $5,000 by the will of Miss Louise C. Rodney.

St. Joseph's Hospital, Reading, Pa., $5,000 by the will of Elizabeth A. Lippe.

For International Peace.—The Carnegie Endowment for International Peace has issued an appeal signed by the trustees for the formation and expression by the people of a strong public opinion which shall influence the minds of the negotiators who are to settle the terms of peace at the end of the present war and which shall establish a new departure in international relations. It is said that a sufficiently strong public opinion might have for its objective that definite rules of national conduct should be agreed on; that a court of competent jurisdiction be established to judge of national conformity to those rules, and that new sanctions should be provided to compel respect for the judgments rendered. The motive and spirit of the new institutions should be the safeguarding of human rights and the perfection of individual liberty.

WAR NOTES

Tetanus Antitoxin for Europe.—At a lecture before the New York Academy of Medicine, February 4, Dr. Matthias Nicoll, Jr., announced that New York City is sending 2,000,000 units of tetanus antitoxin each month to the warring nations in Europe.

French Surgeons at the Front.—In an address before the Paris Surgical Society recently, Professor Tuffier said that of the 14,000 surgeons in the army, 6,500 were at the front. Of these 93 had been killed, 260 wounded and 441 missing; 135 had been mentioned in orders for gallant conduct on the battlefield.

Personal.—The Red Cross badge of honor, second class, has been conferred on Dr. McDonald, chief surgeon of the American Red Cross Hospital unit, Budapest, and on Surgeons Jewett and Miller of the staff of the hospital.——Drs. Ethan F. Butler and Ernest P. Magruder, both of Washington, of the Servian Red Cross unit, have converted a tobacco factory at Gevgalia into a hospital with a capacity of 1,400 beds.

Relief Funds for Belgian Physicians.—In Italy the National Association of public health officials (*medici condotti*) appropriated $700 to start a fund for Belgian physicians, and other medical organizations have contributed, the Consiglio Federale degli Ordini der Medici giving $200 and the Rome ordini giving $100, and public meetings were held at Naples and elsewhere in December to solicit private subscriptions. ——In the Netherlands, relief funds were started early in December, and the *Nederlandsch Tijdschrift* has been publishing regularly since the lists of subscribers.——Our Denmark exchanges also record the donations to the relief fund started in Copenhagen.

Aid for Belgian Physicians.—Dr. Frank F. Simpson, Pittsburgh, treasurer of the committee of American physicians for the aid of the Belgian profession, calls attention in his weekly report to the devastation existent in that country:

"A recent visitor to Belgium says of the desolation there: 'No one who has not been to Belgium within the last five months can picture, can even dimly conceive that country's desolation.

'Wherever our ambulance cars went they met endless processions of refugees: endless, for the straight, flat Flemish roads are endless, and as far as your eye could see the stream of people was unbroken: endless, because the misery of Belgium is endless: the mind cannot grasp it or take it in.

'It was not flight: it was the vast, unending movement of a people crushed down by grief and weariness, pushed on by its own weight, by the ceaseless impact of its ruin.

'I saw six thousand refugees sleeping on straw in the Palais des Fêtes, packed so tight on the floor of the immense hall that there was no standing room between any two of them.

'You could not believe what you saw: you were stunned as if you yourself had been crushed and numbed in the same catastrophe.'

"An American gentleman," says Dr. Simpson, "who saw the food and clothing put into the hold of the steamship *Ynorta*, which took supplies, for the state of Virginia, to the Belgians, crossed the Atlantic on the ship and went into Belgium to watch the distribution of the articles among the people. He has returned and declares: First, that every pound of flour and every article of clothing sent from America by the relief commission is received by a Belgian; and second, that all who get such gifts are in direst need of them. Hunger seems to have broken down all class distinctions in Belgium.

"Captain Green of the steamship *Batiscan*, which sailed with food from Philadelphia on December 6, says that the suffering among the Belgian people cannot be exaggerated.

"Linden W. Bates, manager of the commission for relief in Belgium, states that within a few months the bread lines in Belgium will be 2,500 miles long, which would reach from New York to Salt Lake City.

"Physicians and their families have shared the common fate. Appeals for food, drugs and clothing are numerous and urgent. The resources of your committee have been so limited that we have not felt justified in sending anything but food to our starving colleagues. One hundred and fifty-six physicians and eleven medical societies have thus far contributed to this fund. There are approximately 142,300 physicians in the United States. If each one would contribute even a small sum, it would be possible to supply the necessary food, drugs and clothing. Do not hesitate because your check is not as large as you would like it to be. Contributions of any amount will be welcome.

"Every cent you give will be economically spent for supplies for Belgian physicians and their families. There are no charges for shipping and distribution.

"Not a cent has been spent for stenographer, stationery, stamps, etc."

For the week ending Feb. 13, 1915, the treasurer has received the following contributions:

Dr. Oswald O. Cooper, Hinton, W. Va.		$ 10.00
Dr. Franklin A. Dodge, Le Sueur, Minn.		10.00
Dr. Alfred A. Herzfeld, New York, N. Y.		10.00
Dr. Arthur W. Sieker, Plymouth, Wis.		5.00
Dr. Charles H. Cargile, Bentonville, Ark.		10.00
Dr. Albert A. Bornscheuer, Pittsburgh, Pa.		2.00
Dr. Lyn Waller Deichler, Philadelphia, Pa.		5.00
Dr. Henry T. Goodwin, New York City		5.00
Dr. Henry S. Weigle, Muncy, Pa.		5.00
Dr. James J. Keyes, Brooklyn, N. Y.		5.00
Dr. James I. Johnston, Pittsburgh, Pa.		15.00
Dr. Frederick J. Resseguie, Saratoga Springs, N. Y.		10.00
Dr. Frank H. Jackson, Houlton, Me.		5.00
Dr. Herbert L. Frost, Cleveland, O.		10.00
Dr. Philip St. L. Moncure, Norfolk, Va.		5.00
Dr. Alex. J. Braden, Duluth, Minn.		5.00
Dr. Wendell C. Phillips, New York, N. Y.		75.00
Dr. Russell S. Fowler, Brooklyn, N. Y.		25.00
Dr. John W. Farlow, Boston, Mass.		25.00
Dr. Edwin W. Link, Palestine, Tex.		10.00
Dr. Henry R. Link, Palestine, Tex.		5.00
Dr. Harold Gifford, Omaha, Nebr.		100.00
Jefferson Co. Med. Society, Birmingham, Ala.		50.00
Dr. Edgar R. McGuire, Buffalo, N. Y.		10.00
Dr. Max Einhorn, New York, N. Y.		25.00
Dr. Joseph L. Miller, Thomas, W. Va.		10.00
Dr. David Chester Brown, Danbury, Conn.		10.00
Oshkosh Medical Club, Oshkosh, Wis.		50.00
Dr. George M. Dill, Prescott, Wis.		1.00

Appreciates American Red Cross Work.—The French foreign office has advised the American Red Cross that the minister of war "appreciating the generous and valuable services of the American Red Cross units at Pau" is desirous of sending at least one of these units either to Dunkirk or some other place in the north or east of France where normally a considerable number of badly wounded soldiers are received. It has been ascertained that the two hospital corps units at Pau have many serious cases and the American Red Cross has therefore offered an additional hospital unit for services at Dunkirk or such other place as the French authorities may designate.

FOREIGN

Berlin Prize Goes to Toldt.—The Virchow prize plaque has been awarded by the Berlin Anthropological Society to Prof. K. von Toldt of Vienna, president of the Vienna Anthropological Society.

Medal for Coenen.—The king of Greece has sent to Prof. H. Coenen of Breslau two souvenir medals inscribed with words of gratitude for the services he rendered in the care of the wounded during the recent Greek-Turk and Greek-Bulgarian campaigns. An autographed photograph of the king accompanied the medals.

Pediatrist Appointed Member of Spanish Cabinet.—Dr. G. Alvarez, a well-known pediatrist of Madrid, has recently been appointed a member of the Cuerpo medico of the Real Camara of Spain. This call on the specialist skill of one versed in the diseases and hygiene of children is hailed by the medical and lay press as of promising augury.

The Swedish Medical Association.—This important association has ten memorial endowment funds for charity, three funds for purchasing books and for social purposes, and ten for prizes or appropriations for research work. The Regnell prize for 1914 was awarded to Prof. I. Bang of Lund for his monograph on the residual nitrogen of the blood. The jubilee prize was given to Prof. U. Quensel of the University of Uppsala for his comprehensive and important work, "The Alcohol Question from the Medical Standpoint." The recipient of the Alvarenga prize was Prof. P. Haglund for his study of scoliosis (reviewed in our Foreign Current Literature Department, February 20). The prizes, etc., are open only to Swedish physicians. The Svenska Läkaresällskapet publishes three periodicals: the monthly transactions or *Förhandlingar;* the large and handsome archives or *Handlingar*, and *Hygiea*, a fortnightly general medical periodical. The two latter are indexed and reviewed regularly in our Foreign Current Literature Department.

Deaths in the Profession Abroad.—A. Mermod, professor of ear and throat diseases at the University of Lausanne, aged 62.——L. Guaita, one of the leading ophthalmologists of Italy, professor of this chair at Florence, Italy, died December 30, aged 63. He founded the eye clinics at Bergamo and Siena and reorganized the one at Florence. He published sixty articles or books on various subjects in ophthalmology, and has lately been at work on a large atlas of the eye.——O. K. Sprengel, surgeon-in-chief of the public hospital at Braunschweig and president of the German Surgical Association, succumbed to septic infection, professionally acquired, aged 62. His works on high shoulder, traumatic coxa vara and the laparotomy incision, etc., are well known.——The cable brings word of the death from typhus of Surgeon-General Philip Pack, chief of the medical service in the Austrian army. He contracted the disease during a trip of inspection to the camps of Russian prisoners.——Dr. Moliner of Valencia, Spain, a leading spirit in the organization of the profession, in the campaign against tuberculosis and in the efforts for progress in hygiene and in public health in general. The *Siglo Medico*, which brings the notice of his sudden death, contains also, by a strange coincidence, his last written words—a ringing appeal from him to the profession at large on the necessity and advantages of closer organization of the profession throughout the country.

The Earthquake in Italy.—The *Policlinico* states that large numbers of physicians were among the victims of the earthquake, and those who survived were unable to render proper service because all dressings and drugs were buried under the ruins. Dr. De Sanctis of San Benedetto dug for a whole day in the ruins of what had been the local drug store trying to unearth some dressing material and bichlorid. The physicians connected with the state railroads were the first to bring help to the stricken province, the chief of the service despatching relief trains with dressing materials and drugs from all the larger cities outside of the devastated zone. A well-equipped hospital train with operating room was sent from Rome, and relief trains were soon on their way from Naples, Turin, Milan and Ancona. When the wounded in towns along the railway had been tended, the physicians struck out into the country, finding more victims the farther they walked. The military medical officials were soon on the spot also, and the unharmed local physicians were provided with ample supplies. The traumatic injuries, especially those of the head, were usually found covered with plaster dust, which it was a difficult and tedious matter to clear out. There was not enough antitetanus serum on hand to give all the injured a preventive injection, but hydrogen dioxid and tincture of iodin were used in abundance. The injuries were mostly compound comminuted fractures of the legs, fracture of the clavicle and extensive wounds of the scalp. Those who were dug out of the ruins after having been thus buried for several days were often found suffering from shock, and numbers of them died within a week. In many cases morphin proved remarkably effectual, better than stimulants.

PARIS LETTER

Paris, Jan. 28, 1915.

The War

NUMBER OF MILITARY PHYSICIANS KILLED, WOUNDED AND SICK

At the opening of the formal session of the Société de chirurgie, January 20, Dr. Tuffier, agrégé at the Faculté de médecine de Paris and surgeon of the hospitals, gave statistics concerning the members of the medical profession serving with the army who have been killed or incapacitated. At the end of December, of our 14,000 military physicians, 6,500 were with the armies, 793 were killed, wounded or missing (90 killed, 80 on the battlefield, and 13 dead of wounds; 260 wounded and 440 missing) and 507 were sick. Altogether, 1,300 were killed, missing or incapacitated. The courage and devotion of the medical profession has been recognized by 155 mentions in the order of the day of the army, 15 nominations of officers of the Legion of Honor and 63 nominations of chevalier of the same order. Eleven auxiliary physicians and pupils of the army health service have received a still higher token of the esteem of their chiefs, the military medal.

A MILITARY PHYSICIAN WITH NINETY-SEVEN WOUNDS

Dr. Dercle, a military surgeon who has just received the cross of a chevalier of the Legion of Honor, holds the record for the number of wounds. He bears the marks of ninety-seven. He abandoned his post only when he fell, having received three serious wounds. At present, he is undergoing his convalescence at the military hospital of Val-de-Grâce, where he received the medal awarded to him by the government for his courage and devotion.

HOSPITALITY FOR RELATIVES OF WOUNDED SOLDIERS

Under the presidency of Mme. Pierre Bonnier, M.D., there has just been founded an Oeuvre d' hospitalité aux parents des blessés et malades militaires, intended to facilitate the sojourn in Paris of provincial families whose members have come to Paris to visit wounded relatives who are being cared for in the hospitals of the Assistance publique. Members of the wounded soldiers' families are to receive, through the hospitals, a notice of the organization with a list of the hotels which belong to it. Armed with this notice, the visitors can, on their arrival at the station, claim the help of the agents of the organization, each of whom wears a knot of red and yellow ribbon on the shoulder and who will furnish them with directions and, if necessary, take them to the chosen hotel. These hotels are near the hospitals and offer a reduction of from 40 to 50 per cent. on their rooms to relatives of wounded soldiers. For any person who is in want, a room will be reserved free of charge for two days. At each hotel, and at the corresponding hospital, is a delegate of the organization who will place himself at the disposal of the patient's family during the stay of the visitors in Paris, and after their departure will act as an intermediary between the family and the patient.

TREATMENT OF WOUNDS OF WAR BY VERY DILUTE ANTISEPTIC SOLUTIONS

At one of the last sessions of the Académie des sciences, Dr. J. Danysz of the Pasteur Institute read a report on researches which he has made, drawing his inspiration from theories put forward by Dr. Roux, director of the institute. These investigations tend to show that for certain antiseptics there are dilutions which, though germicidal, are yet stimulating for the growth and reconstruction of the injured tissues. These two actions are found best associated in very dilute solutions of silver nitrate. In numerous cases this method has been used in the last two months in some of the hospitals of Paris and in some Red Cross ambulances; in all cases disinfection has been observed together with a more rapid cicatrization than with the other chemical means hitherto employed although the solutions used were extremely dilute—from 1:200,000 to 1:500,000.

A New Method of Rapid Bacteriologic Diagnosis of Typhoid Fever

This procedure, which permits the rapid diagnosis of typhoid fever and the detection of bacillus-carriers, was reported to the Académie des sciences by Dr. P. Carnot, agrégé professor at the Faculté de médecine de Paris and Dr. B. Weill-Hallé, physician of the hospitals of Paris. A U tube with a constriction in the horizontal portion is used. A layer of sterilized sand is introduced into the tube and two arms are filled with a sterile bouillon. One of the arms of the tube is inoculated with the suspected stools and the tube is incubated at 37 C. Under these conditions the germs introduced with the stools develop, but the typhoid bacilli, being much more motile than the other intestinal microorganisms, traverse the layer of sand and multiply in the second arm of the U tube in which no infected matter has been placed. The character of the bacilli is verified by the agglutination test. The method is very sensitive and allows a precise result to be obtained within a few hours.

The War

THE SANITARY CONDITIONS OF THE BRITISH TROOPS: COMPARATIVE ABSENCE OF TYPHOID FEVER

While presiding at one of the Chadwick Lectures on "War and Disease" by Dr. F. M. Sandwith, Sir Frederick Treves made the statement that our sanitary arrangements in the present war were unprecedented. He says this having in view both the British war in South Africa and the Russo-Japanese War, of both of which he had experience. As a member of the Army Sanitary Committee at the War Office he could speak with assurance on the point. When the history of this war came to be written and read, one of the most astounding and magnificent features in it would be found to be the sanitary precautions that had been taken, and the sanitary measures that had been carried out, to secure the health of our soldiers, and their care in time of disease. But although typhoid might be rendered immensely less by proper education of the soldier, by the care and knowledge of the medical men, and by sanitary arrangements, it could not by these measures be eradicated. A further precaution was needed—inoculation. In South Africa and in the Russo-Japanese War, he was struck by the difference between the soldier who was informed and the soldier who was ignorant. Our men were not informed, and on going up to Ladysmith he confessed it was a dreadful sight to see men drinking water he knew to be polluted. Education had improved matters since then. Sanitary conditions that held good in South Africa were fair for the time; many things were then quite new and many under trial. The following are the latest figures showing the value of inoculation: Since the beginning of the war there have been only 421 cases of typhoid fever among the British troops; 305 were in men who were not inoculated. There have been 35 deaths. Of these deaths, 34 were men who had not been inoculated within two years. Only 1 death occurred among patients who were inoculated, and that man had been inoculated only once. When the nature of the country in which the British troops are operating is borne in mind, the efficiency of the sanitary arrangements will be all the more apparent. The small remaining part of Belgium held by the Allies has been inundated to prevent the advance of the Germans, and in consequence of the rains, the trenches in which the men stand for many hours hold water which extends up to the ankles and even higher.

THE GERMAN PRISONERS IN ENGLAND

The manner in which the German prisoners are cared for in England is shown by the following report by Dr. Athelstane Nobbs, president of the Wandsworth Division of the British Medical Association, who is in medical charge of a ship, used in time of peace for emigrant purposes, now converted into a floating prison: The dietary consists of 1½ pounds of bread, ½ pound of meat, 2 ounces of butter or margarin, ½ pound of potatoes, ½ pound of green vegetables, with tea, milk and gruel. Evening gruel has lately been added, but is not much appreciated. As to bread, there is considerable difficulty in pleasing the prisoners. They clamored for black bread, which they urged was more nourishing than white. Rye was not easy to obtain, but it was eventually obtained.

and it was hoped that all would go smoothly. But apparently English ovens do not lend themselves to the baking of rye bread. Some of the prisoners, who in private life had been bakers, were employed, but to no purpose. After much experimenting the happy medium seems to have been found by making dough composed of 2 parts of whole meal, 1 part of wheat flour, and 1 of rye. This mixture rises fairly well, and is best when of the previous day's baking. There were at first loud clamors for the sausage of the Fatherland which, being unobtainable, is not likely to appear in the menu. In the cookhouse prisoners were at first made trial of, but the inevitable happened. Just as the bakery failed even with German bakers to superintend or advise, so did the cookery prove a slip. Within twenty-four hours of the venture there was an outcry to return to English methods, and it has remained at that ever since. With the exception of the quarters allotted to the guard, the officers and navigators, the prisoners have the run of the whole deck, or rather decks. They have the fair winds of heaven with which to fill their lungs, and hot saltwater baths in moderation. They have never-ending post which brings them parcels—everything except alcohol and shore leave.

Another illustration is furnished by the camp at Stratford, where more than 200 Austrians and Germans are interned. The prisoners are permitted to deck the interior of the buildings with the German and Austrian national colors, to wear a souvenir badge, and to erect a stage at which an elaborate musical and dramatic entertainment was given in honor of the kaiser on his birthday. The title of a one-act musical comedy, "The Jolly Prisoners," is significant. The events were closed by "Die Wacht am Rhein."

ARRIVAL OF JAPANESE RED CROSS CONTINGENT

A Red Cross contingent consisting of two surgeons, a secretary, two chief nurses, twenty nurses and an interpreter have arrived at London in response to the acceptance by the War Office from the Japanese Red Cross. The head of the party is Dr. Suzeki, who served before Port Arthur in the Russo-Japanese War. Dr. Oshima, another member, is a graduate of the Imperial University of Japan, and was actually studying medicine in Germany when war was declared. He managed to escape to London, and went on to Japan, which he left again with his present colleagues. Mr. N. Otsuka was professor at the Disciples' Bible College, Tokyo, and most of the party, including the nurses, have left their civil occupations, and in several cases their husbands or wives. The nurses belong to the Red Cross League of Japan, which, founded about thirty years ago, binds its members, wherever they are, in case of emergency to respond to any call that may be made on them, and to go wherever they may be sent during the period of three years' training and fifteen years' service in the reserve.

SCARCITY OF LEECHES AS A RESULT OF THE WAR

Though leeches are not used in medicine to anything like the extent of former years, serious scarcity has arisen since the war, as the armies are now fighting in some of the best leech areas of Europe.

Traumatic Neurasthenia Without Physical Injury

It has been shown in previous letters that the workmen's compensation act is so comprehensively drawn up that workmen are entitled to compensation for injury under practically any conditions. The following case, which came before the Court of Appeal, shows that physical violence is not necessary for "injury" in the meaning of the act. A collier went to the assistance of a fellow workman who, having been badly injured, was bleeding from the head, face, ears and eyes. He picked him up and carried him away, and the injured man died a few minutes later. The allegation made was that the plaintiff had received a nervous shock which incapacitated him from work and that he therefore suffered from an accident arising in course of his employment. The court decided that the condition was, in fact, the result of an accident while at work. The presiding judge held that the nervous shock produced physiologic injury, and was the result of an accident "arising out of and in course of the employment" (the words of the act).

BERLIN LETTER

Berlin, Jan. 19, 1915.

The War

AWARD OF THE IRON CROSS

The decoration of the Iron Cross of the first class has been bestowed on Professor von Drigalski of Halle, Surgeon-General Schumburg of Hanover, brother-in-law of von Behring, and Privat-Docent Stier of Berlin. In the case of the last named, the decoration was in recognition of the rescue of the wounded when our troops were surrounded and afterward broke through the Russian armies at Lodz late in November.

ORGANIZATION OF MEDICAL SERVICE

With the complete separation of the leadership in our western and eastern theaters of war, the medical affairs of the army in the east have been placed under a special chief in the person of Surgeon-General Kern, also well known as a philosopher. In this way the medical service of the eastern army is completely independent of the surgeon-general of the army, von Schjerning.

A HEALTH SERVICE FOR BELGIUM

A German management of medical affairs of the parts of Belgium now occupied by the Germans has been established under the supervision of Surgeon-General Stechow. Garrison physicians are employed in Antwerp, Brussels, Liége and Namur who, partly assisted by Belgian officers and physicians, have organized a public health service. In the province of Namur a compulsory notification of infectious diseases which was not previously enforced has been introduced by Professor Schilling, who is serving as garrison physician and who was formerly for many years a member of the Robert Koch Institute for Infectious Diseases. The bacteriologic institute which existed in Namur has been adopted as a hygienic examination office for diagnosis. This institution heretofore was available only for private examination to the Belgian physicians. Furthermore, the establishment of sewerage which was formerly limited, has been begun. A health commission has been appointed in which German and Belgian physicians, under the presidency of the garrison physicians, consult together on matters of public health. Most Belgian hospitals which were originally monasteries had to be brought to the standard of modern hospital requirements. Sanitary closets were established, electric light introduced and Roentgen cabinets, dental departments, permanent baths and medicomechanical apparatus, etc., provided. Moreover, in some places, isolation for infectious diseases had to be provided. Typhoid patients are, as far as possible, collected at Spa. There is in Belgium an enormous prevalence of venereal diseases. This has occasioned a not inconsiderable inconvenience for our soldiers. For this reason, special attention has been devoted to a methodical campaign against this plague. In the city of Chauny, the brothel has been closed since the beginning of the war, but a similar business was established in two houses of the city, which naturally produced a nuisance, as the conveyance of infection was thereby promoted. For this reason these two houses were closed and the sick prostitutes found there and other women affected with venereal diseases were confined in another house and treated. As soon as an infection is found in a soldier, the source of infection is carefully determined and the woman from whom the infection has arisen is permanently confined. The soldiers are expressly notified of the dangers of sexual intercourse with especial reference to the circular of the German society for combating sexual diseases, and continence is recommended.

NERVOUS AND MENTAL DISEASE

The Berlin psychiatrist, Albert Moll, recently reported at an evening meeting for the consideration of military medical affairs on the results of a tour for psychiatric study through the western theater of war, the hospitals of Northern France and Belgium. Altogether relatively few insane were found, while nervous disturbances appeared somewhat more frequently. Cases of imbecility were only rarely observed. The reason for this is, first, the better education in psychiatry of military surgeons, who immediately reject such patients, and second, the fact that the registers of the subsidiary schools for feeble-minded and those of the insane asylums have been made accessible to the recruiting boards. A few cases of primary alcoholic insanity have been received in the special wards of the hospitals. Moll saw during his trip only two drunken soldiers. He holds the provision that complete abstinence be not required during the campaign to be fully justified, but regards it as desirable that presents of alcohol to the soldiers should be distributed by their superiors. In view of the sanitary conditions in France and Belgium and of the composition of the water that is available, the addition of wine to the water is required. In Liége, where a nervous department has been established in the hospital, only nineteen patients had been admitted up to the middle of November. Among these were three epileptics, three cases of anxiety neurosis and six of alcohol psychosis. This is a small number considering the large number of soldiers who are stationed in that neighborhood or pass through it. In Brussels, 120 patients were treated in the department, of whom, however, a great number were affected with organic nervous diseases, such as shot wounds of the nerves or cases of apoplexy, and also five cases of primary alcoholic insanity, thirteen of paralysis, seventeen of epilepsy and seventeen of hysteria. In a large army hospital in the neighborhood of Argonne that received a very large number of soldiers, only ten or twelve cases of insanity were observed by a psychiatrist who had seen all the patients. Cases of exhaustion psychosis have been observed, as they were in the Russo-Japanese War. Moll, however, would include these with hysteria rather than genuine insanity. Diagnosis is difficult in the field where any sort of history is lacking, and also it is difficult to decide where the treatment of cases of insanity can best be carried on. Transportation home is best secured in separate departments of the hospital train which are provided with specially trained nurses.

FROM SIR WILLIAM OSLER

Oxford, Feb. 3, 1915.

Medical Notes on England at War

FROST-BITES AND COLD-BITES

The outstanding feature of the recent admissions to the hospitals from the front has been frost-bite, a very unusual condition in British practice. The cold has been severe in Northwest France and Belgium; the men have had long exposures in the trenches, from the effects of which thousands are suffering with sore feet. To wear boots and stockings continually for a week or ten days soaked in cold mud or water and mud, passing long hours in the upright position, naturally causes vasomotor paresis with swelling, and the prolonged stasis has led in not a few cases to necrosis. The cases varied extremely. In the first place there may be nothing more than aggravated chilblain, with the stages of protracted venous stasis, edema, bullae and superficial necrosis. A lad at the Canadian Hospital, Beechborough Park, had slight tenderness of his feet which had only been swollen and blue, but over the backs of both hands and knuckles were areas of superficial necrosis. He had been in the trenches for days, his hands had been swollen, particularly the backs, and he was completely incapacitated.

Secondly, there have been cases of genuine frost-bite; the temperature was protractedly low, and widespread necrosis followed; but several men with necrosis of the toes assured me that the water in which they had stood had not been frozen. In the sequel of events no doubt all of these lacked the preliminary complete anemia of ordinary frost-bite. Gangrene never follows this stage directly, but the succeeding condition of stasis in veins and capillaries. A very common form has been great swelling, with lividity, blackness of the toes, with a slight necrosis of the superficial skin of the pads, or shedding of the nails. As in Raynaud's disease, the final condition is often very much better than one could have anticipated from the appearance of the feet at first. A man at Paignton had a curious distribution of the necrosis, confined to the sole of one foot.

Thirdly, with these conditions, with which all are familiar, there have been an unusually large number of cases to which the term "cold-bite" is more applicable. The men return with swollen feet, vasomotor paresis, not necessarily with much pain but with disability due more to the swelling, and sometimes to the great stiffness of the toes. The desquamation of the skin and hemorrhages beneath the nails indicated that this was a sequel of much more serious condition. More unusual cases have been without any obvious change, the feet looking normal but with an extreme degree of cutaneous hyperesthesia, so that the slightest touch caused wincing and the feet had to be constantly protected with a cradle. Sometimes the pain was spontaneous, or it would come on at night; but in many instances it was brought out only on attempting to stand, or when the patient was touched, or the foot moved. In several cases it was a "stocking" hyperesthesia reaching just above the ankle. One patient in the convalescent home at Blenheim Palace had evidently suffered intensely, and was badly knocked out in his nervous system. Others have shown marked neurasthenic or even hysteric manifestations. The truth is, the trenches have been a veritable hell, and it is not surprising that a good many of the men show signs of severe nervous shock.

THE LOW MORTALITY AMONG THE WOUNDED

It is intensely interesting to see a set of severe cases some weeks after their admission. Extraordinary results follow even in the severest type of cases. At the American Hospital, *patients whom I never expected to see alive were* up and about and doing remarkably at the end of a month. A man with the surface of the trochanters bare and the lower end of his thigh infected severely had the wound cleaned, and a nice amputation made, with a good stump. A man with a part of the sacrum blown away and the rectum exposed from behind had gained 10 or 12 pounds in weight, the wound was healing rapidly and the fecal fistula had healed. One is immensely impressed with the good results of treatment and the very low rate of mortality. At the Base Hospital here, among more than 3,000 cases there have been about a dozen deaths. At the Cambridge Hospital among the first 3,500 patients admitted only fifteen died—a mortality of 0.4 per cent. At the American Hospital, Paignton, there has been only one death among 700 patients—a mortality of 0.14 per cent. It has been very satisfactory to note the absence of tetanus in the recent admissions and that cases of gas gangrene have been fewer.

AN ANEURYSM CASE

I mentioned in my first letter the case of a Belgian at the Beechborough Canadian Hospital in whom the bullet passed through the mouth under the jaw, beneath the skin of the neck, and lodged below the left clavicle; the cervical triangle was filled with a pulsating mass. When first seen it looked like an ordinary traumatic aneurysm, and I felt sure that an artery must have been wounded; but after Dr. Armour had removed the bullet and relieved the tension, the pulsation ceased, and the second time I saw the patient there was nothing but the firm indurated swelling above the clavicle with disability of the arm from pressure on the nerves. Then he began to bleed freely from the throat and from the wound, and it was quite evident that an artery had been opened. Dr. Armour operated and found that the bullet had nicked the subclavian artery, which he tied successfully, and the man has made a complete recovery.

CEREBROSPINAL FEVER

Medically, the most disturbing incident has been the outbreak in various camps of cerebrospinal fever, a rare disease in this country. There had not been a very bad epidemic during the nineteenth century, but in 1905-1906, Belfast and Glasgow suffered severely, and there has been an increase in the sporadic cases during the past three years. The first Canadian contingent apparently brought the disease with them, as there were four cases at Valcartier and three cases on the voyage. There was no additional case until recently, and they have had in all about twenty-five or twenty-six, with eleven or twelve deaths. I went last week to the camp at Salisbury to see the cases. The weather has been appalling, much wind and more rain, and everywhere the mud has been ankle-deep. At the General Hospital, Netheravon, under the care of Dr. Murray Maclaren of St. John and Dr. F. G. Finley of Montreal, there were many cases of bronchitis, bronchopneumonia and rheumatism. Most of the men, however, looked very fit and seemed to have stood the hardships very well. A new hospital had just been opened for the cerebrospinal fever cases, of which there were eleven under treatment. I found a well-equipped laboratory and a full staff of workers under Dr. Arkwright of the Lister Institute, who has done much work on the meningococcus. Dr. Ellis, who has been at the Rockefeller Hospital, New York, for the past four years and who is an expert in all methods of intrathecal treatment, was in charge of the clinical work. They had only just begun a systematic investigation of the contacts, and when I left they had not detected any carrier. It is not likely that the epidemic will prove serious. It is alarming, though, as there is another infected camp not far away in the English troops, and in the city of Salisbury itself there have been ten cases and seven deaths. I was afraid at first that the Canadians were responsible for bringing the infection, but it is evident that, as is usually the case, sporadic outbreaks are occurring in different parts. There have been a few cases at Haslar; I saw two cases at the Millbank Hospital, both from the Eastern counties, and on the thirtieth I visited the Shorncliffe Camp, where they have had eight deaths, and a few cases remained in hospital. It is interesting that this is the only place during the nineteenth century that the disease appeared among soldiers.

TYPHOID FEVER

There is extraordinarily little typhoid fever among the recruits or in the patients in the hospitals from the front. Sir Frederick Treves in the *Times* of to-day gives the returns of the British troops in the present campaign—421 cases, 305 in men who were not inoculated. In the 421 cases there have been thirty-five deaths; of these thirty-four were men who had not been inoculated within two years; only one death occurred among patients who were inoculated and that man had been inoculated only once. The "Anti's" are causing a great deal of trouble in distributing their pernicious literature among the soldiers. It is a thousand pities the government does not take its courage into both hands and order compulsory inoculation. It is evidently going to be a "long, long way to Tipperary" in this war, and should typhoid fever within the next eighteen months play the same rôle as it did in the South African War, the bacillus of Eberth might very well be one of the determining factors in deciding on which side victory will fall.

Everywhere preparations are in progress for the spring and summer campaign. New hospitals are being built to meet the heavy demand when, for the first time in its history, this country will have more than 1,500,000 in the fighting line. We have had orders for another 500 beds in Oxford, which will be arranged for in barracks in the Radcliffe Observatory Field close to the Radcliffe Infirmary. Waldorf Astor, Jr., has given his beautiful place at Clevedon on the Thames as a Canadian Base Hospital, and between the house and the barracks erected on the grounds there will be 500 beds.

DEATH OF PROFESSOR VAN GEHUCHTEN

A tragic event, of which you have already heard, was the death of Professor Van Gehuchten. He had settled very happily at Cambridge working at the Research Laboratory with Dr. Strangeways, and we were so glad to be able to put him on the Rockefeller list. He died suddenly after an operation for volvulus. How the poor fellow and his family suffered at the Louvain tragedy is told in the *British Medical Journal,* January 16.

WILLIAM OSLER.

Association News

THE SAN FRANCISCO SESSION

Announcement by the Subcommittee on Hotels Regarding Reservations in Advance

The local Committee on Arrangements for the San Francisco session requests those who contemplate attending to secure their accommodations as early as possible. The committee has full assurance that those who attend can depend on the rates hereinafter quoted. The subcommittee on hotels is being assisted by the official hotel bureau, established by the exposition management, together with a committee of hotel men representing the hotel interests of San Francisco and vicinity. The purpose of this bureau is to afford protection to exposition visitors (which of course includes those attending the meeting of the American Medical Association) against increased or unreasonable hotel rates, and to provide an official bureau through which intending visitors to San Francisco in 1915 may secure hotel reservations at desirable rates, either in advance or on arrival. No hotel is admitted to registration in the bureau until it has filed its rates in full, and until these rates have been passed on by an unprejudiced committee as reasonable for location and service given. Hotels registering with the bureau guarantee that the rates quoted will not be directly or indirectly increased during 1915. The subcommittee on hotels, cooperating with this bureau, will undertake to secure reservations for all those addressing communications to it.

All hotels in San Francisco, with a few exceptions in the residence district, are less than eight years old and are modern in all respects, so that no one need fear that in engaging accommodations at the lower priced hotels, he will not find clean and modern quarters. The local subcommittee on hotels desires to avoid having too many rooms engaged for one person, and advises that in each of the hotels there is a limited number of single rooms and that in certain other hotels the same price will be charged whether the room be occupied by one or two persons. Where but one rate is quoted, it is the minimum rate. The minimum rate quoted for two persons in one room is for a room with a double bed. Twin beds call for a slightly higher tariff. Blocks of rooms have been engaged at all the leading hotels dating from June 19, the Saturday before the meeting, and these will be apportioned in order of application—first come, first served.

In submitting the present list of hotels, the subcommittee on hotels advises that a longer list will be announced later, as the Hotel Bureau has not yet all the data compiled, and it is expected that the register of the bureau will include several hundred hotels.

The local Committee on Arrangements requests that those desiring to reserve accommodations shall use the form appended to the list of hotels which appears on advertising page 21 of this issue, and mail their request to the official Hotel Bureau at 702 Market Street, San Francisco. On receipt of this request, the accommodations asked for, or those as nearly like the accommodations requested as it is possible to secure, will be reserved. The subcommittee on hotels urges Fellows to make these reservations through the subcommittee on hotels, or the official Hotel Bureau.

F. B. CARPENTER, Chairman, Subcommittee on Hotels.

The hotels listed below have already been assigned as headquarters:

General Headquarters	Palace
Medicine	Palace
Surgery, General and Abdominal	St. Francis
Pathology and Physiology	Bellevue
Stomatology	Plaza
Dermatology	Granada
Preventive Medicine and Public Health	Clift
Genito-Urinary	Manx
Hospitals	Inside Inn
Orthopedic Surgery	Stewart

Marriages

Frank Riegel Wentz, M.D., Allentown, Pa., to Miss Kathryn M. Shoemaker of Chestnut Hill, Philadelphia, February 20.

Francis William Doyle, M.D., South Deerfield, Mass., to Miss Marie Josephine McCormick of Waltham, Mass., February 3.

Frank Mason Dillard, M.D., Mineral, Va., to Miss Evelyn Wilson Dixon, at Dewberry, Hewlett, Va., Dec. 22, 1914.

Thomas Reuben Keller Gruber, M.D., Cleveland, to Miss Alma Rennick of Columbus, Ohio, February 1.

Francis Joseph Pelant, M.D., Solon, Ia., to Miss Minnie Arbes of New Ulm, Minn., February 9.

John Joseph Condrick, M.D., to Miss Edith J. Cosgrove, both of Brockton, Mass., February 1.

Jesse Harper Lander, M.D., Greenville, Tex., to Miss Elizabeth Collier Floyd, February 4.

John J. Ryan, M.D., St. Paul, to Miss Edwina Hurlbut of Oconomowoc, Wis., February 4.

Clarence Walter Hall, M.D., to Miss Media Swennes, both of Denver, Colo., recently.

Deaths

Dudley Sharpe Reynolds, M.D. University of Louisville, Ky., 1868; a Fellow of the American Medical Association and one of the most prominent ophthalmologists of the South; died at his country home near Louisville, February 4, from cerebral hemorrhage, aged 72. He was a native of Bowling Green, Ky., and served during the Civil War as assistant surgeon of U. S. Volunteers; after his graduation and a term of study abroad, he returned to Louisville where he practiced his specialty of diseases of the eye, ear, nose and throat for nearly half a century. From 1874 to 1901, he was professor of ophthalmology and otology and medical jurisprudence in the Hospital College of Medicine, Louisville, and was president of the faculty of the institution from 1891 to 1893. He was surgeon to the Louisville City Hospital from 1872 to 1892 and local surgeon of the Monon System from 1894 to 1899. His society activities included the chairmanship of the Section on Ophthalmology of the American Medical Association in 1880-1881, the presidency of the Mississippi Valley Medical Association in 1888 and the treasurership from 1899 to 1901. Dr. Reynolds was a specialist of wide reputation and of great skill; a teacher and writer of force and ability, a wise counsellor and a man universally beloved and esteemed.

Samuel Wood Langmaid, M.D. Harvard Medical School, 1864; a member of the American Laryngological Society and a well-known specialist on diseases of the throat and nose of Boston; a member of the Massachusetts Medical Society; acting assistant surgeon of volunteers during the Civil War, and later in the U. S. Marine Hospital Service; physician to the throat department of the Massachusetts General Hospital; for several years president of the Harvard Musical Association; died at his home in Brookline Mass., February 3, aged 77.

Louis A. Rodenstein, M.D. University of Pennsylvania, Philadelphia, 1859; a veteran of the Mexican War and surgeon of U. S. Volunteers during the Civil War; later surgeon of the Twenty-Second Infantry, N. G., N. Y.; a member of the New York Board of Education and Board of Police Surgeons; one of the founders of the Manhattan General Hospital in 1885 and surgeon-in-chief to that institution; died at his home in New York City, February 2, aged 80.

Abram Trego Shertzer, M.D. University of Maryland, Baltimore, 1869; fleet surgeon of U. S. Naval Volunteers during the Civil War and staff surgeon in the German service during the Franco-Prussian War; a practitioner of Baltimore for nearly fifty years; local surgeon to the Pennsylvania System and the Baltimore City Railroad; died at his home in Baltimore, January 22, from heart disease, aged 70.

D'Orsay Hecht, M.D. Northwestern University Medical School, 1898; associate professor of nervous and mental diseases in this college; attending neurologist Michael Reese, Wesley and other hospitals of Chicago; a Fellow of the American Medical Association; president of the Mississippi Valley Medical Association 1913-14; a member of various neurologic and psychologic societies; died suddenly at his home in Chicago, Feb. 16, 1915, of angina pectoris, aged 41.

Robert Shoemaker Dana, M.D. Jefferson Medical College, 1857; surgeon of the Ninth Pennsylvania Volunteer Cavalry and One Hundred and Seventh Pennsylvania Volunteer Infantry during the Civil War; at one time medical director of the Department of New Jersey, G. A. R.; for several years treasurer of the Morrisville (Pa.) Rubber Works; died at his home near Morrisville, February 1, from senile debility, aged 82.

William H. Rowe, M.D. Rush Medical College, 1882; a Fellow of the American Medical Association and a member of the Association of Military Surgeons of the United States; formerly vice-president of the State Board of Health; surgeon-general of Minnesota since 1910; for several terms mayor of St. James, Minn., and president of the St. James Hospital; died in that institution, February 4, from nephritis, aged 56.

George Bailey Little, M.D. Rush Medical College, 1873; president of the Burlington, Iowa, Hospital Training School for Nurses; and for forty-two years a practitioner of Burlington; once president of the Des Moines County Medical Society and for eight years a member of the Burlington School Board; died at his home, January 31, from cerebral hemorrhage, aged 63.

Cyrus Fogg Brackett, M.D. Medical School of Maine, Brunswick, 1863; professor of chemistry in his Alma Mater from 1864 to 1873; professor of physics at Princeton University for thirty-five years, and since 1908 emeritus professor; a member of the American Philosophical Society and American Physical Society; died at his home in Princeton, January 29, aged 81.

Jacob Huggins, M.D. University of Pennsylvania, Philadelphia, 1860; a charter member of the Medical Association of the State of Alabama and vice-president in 1891 and 1892; a member of the state board of censors in 1898; for three years surgeon in the Confederate service during the Civil War; died at his home in Newbern, Ala., February 1, aged 77.

Edmund Dulin Laughlin, M.D. Miami Medical College, Cincinnati, 1868; Bellevue Hospital Medical College, 1872; for several terms a trustee of the Indiana Medical College and once vice-president of the Indiana State Board of Health; for many years a practitioner of Orleans, Ind.; died in the home of his son at Evansville, February 6, aged 87.

Philip J. Wardner, M.D. Rush Medical College, 1857; of Cleveland, Ohio; surgeon of the Fifty-Seventh and later of the One Hundred and Twentieth Illinois Volunteer Infantry during the Civil War; for more than thirty years retired from practice and in business in Cleveland; died at his home in that city, Dec. 20, 1914, from bronchitis, aged 82.

Patrick H. Caney, M.D. Kentucky School of Medicine, Louisville, 1892; a Fellow of the American Medical Association; physician to the Knox County (Ind.) Infirmary and secretary of the Vincennes Board of Health; for three terms coroner of Knox County; died at his home in Vincennes, Ind., January 30, from lobar pneumonia, aged 52.

Daniel Clark Stillians, M.D. Chicago Medical College, 1869; one time president of the Alumni Association of his Alma Mater; a Fellow of the American Medical Association; a veteran of the Civil War; until the past four years a resident of Chicago; died at his home in Redlands, Cal., February 12, aged 74.

George Howard Hungerford, M.D. University of Pennsylvania, Philadelphia, 1909; a Fellow of the American Medical Association; medical examiner for the Pennsylvania Railroad Company in Philadelphia; died in the German Hospital in that city, February 1, after an abdominal operation, aged 29.

Zachary Taylor Funk, M.D. Kentucky School of Medicine, Louisville, 1876; once president of the Harrison County (Ind.) Medical Society, treasurer of Harrison County and secretary of the Board of Health of Corydon; a veteran of the Civil War; died at his home Corydon, Nov. 19, 1914, aged 67.

Frank Elmer Hill, M.D. Western Reserve University, Cleveland, 1881; for thirty-two years a practitioner of Buffalo; supreme medical director of the National Order of Buffaloes, and Sovereign Medical Director of the Order of Saturn; died at his home in Buffalo, February 3, aged 55.

Bascom Kavanaugh, M.D. University of Texas, Galveston, 1913; and later assistant physician at the State Quarantine Station; who was shot near his home in San Augustine, Tex., January 7; died January 15, aged 32.

Frank Clary Anderson, M.D. Vanderbilt University, Nashville, Tenn., 1901; formerly a practitioner of Arkansas, Alabama and Colorado; died in Brookwood, Ala., January 11; from pulmonary tuberculosis, aged 34.

J. G. Lapp (license, years of practice, Ohio, 1896), a member of the Ohio State Medical Association; auditor of Monroe County, Ohio; died at his home in Woodsfield, Ohio, about January 24, from heart disease.

Joseph Tottenham Cook, M.D. Homeopathic Hospital College, Cleveland, 1881; attending physician to the Buffalo Homeopathic Hospital; died at his home in Buffalo, January 18, from facial erysipelas, aged 59.

Jonathan N. Faust, M.D. Jefferson Medical College, 1867; a member of the Medical Society of the State of Pennsylvania; died at his home in Reynoldsville, Pa., Dec. 26, 1914, from cerebral hemorrhage, aged 70.

Isaiah H. Herring (license, Forty-Eighth Judicial District Board, Texas, 1901), formerly a member of the State Medical Association of Texas; died at his home in Fallon, near Mexia, Tex., January 13, aged 44.

Charles Pickney Hanson, M.D. Chattanooga (Tenn.) Medical College, 1905; formerly a member of the Arkansas Medical Society; died at his home in Berea, Ark., January 23, from tuberculosis, aged 33.

John Borough, M.D. Homeopathic Hospital College, Cleveland, 1874; a veteran of the Civil War; for forty years a practitioner of Mishawaka, Ind.; died at his home Dec. 31, 1914, from nephritis, aged 71.

John R. McLaurin, M.D. Louisville Medical College, 1884; a practitioner and druggist of Toomsuba, Miss.; died at his home in that place, January 5, from the effects of poisoning by carbolic acid, aged 56.

Charles Dudley Morrow, M.D. Lincoln (Neb.) Medical College, 1895; a practitioner and druggist of Prosser, Neb.; died in a hospital in Hastings, Neb., January 9, as the result of a nervous breakdown.

George Ernest Millichamp, M.D. University of Toronto, Ont., 1895; formerly chief medical examiner of the Union Life Assurance Company, Toronto, Ont.; died at his home in that city, January 7.

James Graeme Richardson, M.D. Manitoba Medical College, Winnipeg, 1911; of Winnipeg; died in the Winnipeg General Hospital, recently, from septicemia following disease of the ear, aged 28.

Winfield Scott Norcross, M.D. State University of Iowa, College of Homeopathic Medicine, Iowa City, 1886; a veteran of the Civil War; died at his home in Auburn, Maine, January 7, aged 70.

Chester Monroe Baker, M.D. Long Island College Hospital, Brooklyn, 1896; a member of the Massachusetts Medical Society; died at his home in Hyannis, Mass., Dec. 12, 1914, aged 39.

Charles W. Patton, M.D. Kansas City (Mo.) Medical College, 1888; a member of the Missouri State Medical Association; died at his home in Mooresville, January 26, aged 62.

John Calvin Craig, M.D. University of Michigan, Ann Arbor, 1873; of Liberty, Ill.; died in Conway, Ark., Dec. 14, 1914, from sarcoma of the jaw, following an operation, aged 66.

Franklin Thomas Moore, M.D. Jefferson Medical College, 1897; a member of the Staff of the Syrian Protestant College, Beirut, Syria; died suddenly in that place, January 15, aged 48.

Charles E. Reese, M.D. Medical College of Ohio, Cincinnati, 1885; local surgeon of the C. and M. V. Railroad; died at his home in Cedar Heights, near Lancaster, Ohio, Nov. 1, 1914.

Samuel T. Baldridge, M.D. State University of Iowa, Iowa City, 1887; a member of the Illinois State Medical Society; died at his home in Chicago, February 2, aged 52.

William G. Schmidt, M.D. Missouri Medical College, St. Louis, 1891; a practitioner and druggist of Quincy, Ill.; died at his home, January 16, from disease of the liver, aged 54.

Joseph Kalisher, M.D. New York University, New York City, 1881; a Fellow of the American Medical Association; died at his home in New York City, January 27, aged 57.

John J. Rigg, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1885; died at his home in Fort Madison, Iowa, January 18, from cerebral hemorrhage, aged 61.

Richard Runyan Rogers, M.D. University of Pennsylvania, Philadelphia, 1862; once surrogate of Mercer County, N. J.; died at his home in Trenton, N. J., January 14, aged 91.

Bradford Patterson, M.D. American Medical College, Cincinnati, 1865; surgeon of volunteers during the Civil War; died at his home in Barrie, Ont., Nov. 8, 1914, aged 94.

David Hume McDonald, M.D. University of Louisville, Ky., 1855; for fifty-six years a practitioner of Quincy, Ind.; died at his home in that place, January 17, aged 83.

Thomas A. Gamble, M.D. American University of Pennsylvania, Philadelphia, 1873; a veteran of the Civil War; died at his home in Troy, Pa., January 17, aged 70.

Henry W. McLaughlin, M.D. College of Physicians and Surgeons, Baltimore, 1885; died at his home in Marietta, Ohio, January 20, from locomotor ataxia, aged 54.

Benjamin Ewell Keys, M.D. University of Nashville, Tenn., 1900; a practitioner and druggist of Fate, Tex.; died at his home, January 5, from pneumonia, aged 50.

Walter Bradley Hill, M.D. Jefferson Medical College, 1864; formerly of St. Louis; died at his home in San Jose, Cal., January 14, from senile debility, aged 72.

Louis Lohman, M.D. University of Giessen, Germany, 1846; a physician and druggist of Kimmswick, Mo.; died at his home in that place, January 8, aged 94.

Thomas Pope Dudley Pound, M.D. Louisville (Ky.) Medical College, 1875; died at his home in Jeffersontown, Ky., January 9, from heart disease, aged 70.

L. G. Bombarger, M.D. Memphis Hospital Medical College, 1901; was found dead in his office, January 15, from accidental gas asphyxiation, aged 46.

Herbert James Pratt, M.D. Harvard Medical School, 1868; a musician and linguist of Plymouth, Mass.; died at his home in that place, January 21, aged 72.

John T. Digges, M.D. Georgetown University, Washington, D. C., 1869; a Confederate veteran; died at his home in La Plata, Md., January 13, aged 73.

Francis Alfred Comfort, M.D. University of Michigan, Ann Arbor, 1866; died at his home in Logan, Neb., January 21, from heart disease, aged 73.

Charles William Brunner, M.D. Long Island College Hospital, Brooklyn, 1891; died at his home in Williamsburg, Brooklyn, January 22, aged 59.

Leonard W. Carpenter, M.D. Homeopathic Hospital College, Cleveland, 1865; died at his home in Trumansburg, N. Y., Nov. 8, 1914, aged 81.

George W. Burleigh, M.D. Indiana Eclectic Medical College, Indianapolis, 1887; died at his home in Los Angeles, Cal., January 19, aged 79.

William Melandston Nead, M.D. Homeopathic Hospital College, Cleveland, 1884; died at his home in Albany, N. Y., Dec. 26, 1914, aged 55.

Scott Fulton, M.D. Columbus (Ohio) Medical College, 1892; died at his home in Columbus, Ohio, January 15, from pneumonia, aged 50.

Robert Davis Reynolds, M.D. University of Alabama, Mobile, 1880; died at his home in Ozark, Ala., January 12, from heart disease.

William Havens, M.D. Michigan Homeopathic Medical College, Lansing, 1871; died at his home in St. Johns, Mich., January 10, aged 84.

Charles H. L. Johnston, M.D. L.R.C.S. Edinburgh, 1865; died at his home in St. John, N. B., January 18, from heart disease, aged 70.

J. E. Cooper, M.D. Louisville Medical College, 1895; died at his home in Golden, Tex., January 19, from cerebral hemorrhage.

William Lewis Lett (license, Oklahoma, 1908), also a druggist; died at his home in Lamar, Okla., January 1, aged 61.

Maxime Landry, M.D. Tulane University, New Orleans, 1893; of New Orleans; died in Mandeville, La., January 14, aged 42.

Frédéric Lefils, M.D. Laval University, Quebec, 1892; died at his home in Montreal, January 8, aged 46.

Joseph S. McKinley, M.D. University of Nashville, Tenn., 1867; died at his home in Cordova, Tenn., January 12.

The Propaganda for Reform

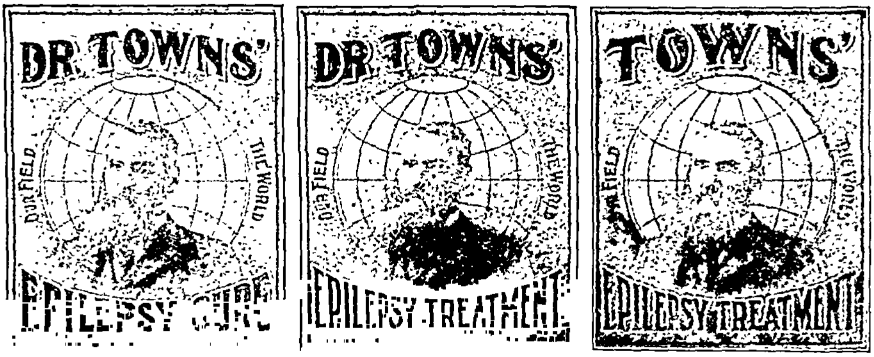
In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

TOWNS' EPILEPSY TREATMENT

Another Fraudulent Bromid Mixture

Towns' Epilepsy Treatment is marketed by the Towns' Remedy Company of Milwaukee, Wis. A few years ago this preparation was known as "Dr. Towns' Epilepsy Cure" and was sold from Fond du Lac, Wis. Then came the Food and Drugs Act, which made false statements on the trade package come high, and as Towns' "patent medicine" is not and never was a "cure" the name of the product was changed to "Towns' Epilepsy Treatment." The Towns concern did not move directly from Fond du Lac to Milwaukee but was for a time located at Baltimore, Md.

The method by which the Towns alleged cure is brought to the attention of prospective victims is typical of the mail-order faker. Leaflets and "follow-up letters" are sent to those who answer the Towns advertisement. In addition to the usual testimonial, common to the "patent medicine" fraternity, Towns sends out "endorsements" of his nostrum from "authorities." One of these endorsements is, according to Towns, "from the highest authorities known." The "highest authority" referred to is Willard H. Morse, M.D., F.S.Sc. (Lond.), etc. Morse's name, as most of The Journal readers know, appears on alleged analytical reports and testimonials for numerous fraudulent preparations: consumption cures, epilepsy cures, rheumatism cures, cures for blindness—these are but a few of the fakes that have in their advertising armamentarium so-called chemists' certificates and "professional endorsements" bearing Morse's name. Another alleged endorsement of Towns' "cure" is an "editorial" entitled "Plain Truth About Proprietary Remedies" from the *American Journal of Health*. This publication was one of those journalistic parasites that batten on quackery. In a government report published a few years ago the federal officials made this statement:



The Towns label in its progress toward comparative truthfulness. *"Dr.* Towns' Epilepsy *Cure"* first became *"Dr.* Towns' Epilepsy *Treatment"* and is now simply "Towns' Epilepsy Treatment."

> "It appears by satisfactory proof . . . that this *American Journal of Health* is not a medical journal of good standing, and that it is simply a fraudulent publication printed to sell paid advertisements to various medical concerns doing a mail-order business, and to be then used by such concerns as an endorsement of a medical publication."

Apparently the Towns concern, in common with most medical mail-order frauds, disposes of its "sucker list" when such lists have no further financial value. At any rate it is a matter of government record that a fraudulent "epilepsy cure" of Cincinnati put out of business by the federal officials some time ago declared that it purchased the names of possible victims from Dr. Towns of Fond du Lac.

A bottle of Towns' "patent medicine" was submitted to the Association laboratory for examination. The chemists report:

CHEMISTS' REPORT[1]

One original bottle of "Towns' Epilepsy Treatment," manufactured by the Towns Remedy Co., Baltimore, Md., was submitted to the chemical laboratory for examination. The bottle contained a brown liquid, having extractive matter present, and with an odor of cinnamon and valerian. The specific gravity of the liquid at 15.6 C. was 1.2505. Qualitative tests demonstrated the presence of the following: Alcohol, ammonia, potassium, sodium, bromid, chlorid, iodid and sugar. Quantitative determinations yielded the following:

Alcohol (by volume)	1.00 per cent.
Ammonia (NH_3) (by weight)	1.82 per cent.
Potassium (K^+) (by weight)	2.98 per cent.
Sodium (Na^+) (by weight)	1.39 per cent.
Bromid (Br^-) (by weight)	12.81 per cent.
Chlorid (Cl^-) (by weight)	3.12 per cent.
Iodid (I^-) (by weight)	0.46 per cent.
Sugar (Sucrose) (by weight)	5.42 per cent.

Calculating from the bromid and iodid determinations, each dose, 1½ teaspoonfuls (1½ fluidrams), approximates the equivalent of 21.3 grains potassium bromid and 0.78 grain (about ¾ grain) potassium iodid. The daily dose (6 teaspoonfuls) corresponds to 85.2 grains potassium bromid and 3.12 grains potassium iodid. Considerable chlorid is also present, equivalent to approximately 6 grains sodium chlorid in 1½ teaspoonfuls, or 24 grains in the daily dose (6 teaspoonfuls).

Evidently this "epilepsy cure," in common with other nostrums of the same kind, depends for its action on the presence of bromids. And Towns has made the claim that he "can cure ninety-six in every hundred cases" of epilepsy! In a card sent out by the Towns Remedy Company the public is led to infer that the nostrum has the endorsement of federal judges. Whether this is true we do not know. It is a matter of court record, however, that the federal authorities prosecuted the Towns concern for making false and misleading claims for the preparation. When brought before the federal judge the Towns concern pleaded guilty and was fined.

ARTICLES REFUSED RECOGNITION

Reports of the Council on Pharmacy and Chemistry

Below appear abstracts of the Council's action on articles refused recognition which were not deemed of sufficient importance to require a lengthy report. Previous instalments of abstracts appeared in The Journal, Nov. 14 and 21, Dec. 12, 1914, Jan. 2 and 30, 1915.

Virol

Virol, sold in the United States by the Etna Chemical Company, is put out by Virol, Ltd., London, England. It is said to be

> "A preparation of bone marrow, red bone marrow of medullary structure of ox rib and calf bones, eggs, malt extract, and lemon syrup made from fresh fruit."
>
> "Marrow fat is emulsified with extract of malt, lemon syrup and eggs, it is further enriched with soluble phosphates of lime, iron and soda, and glycerine solution of red bone marrow."

---

[1] This is a condensed report of the chemists' findings. The details of analysis will appear in the Reports of the Chemical Laboratory of the American Medical Association for 1914.

Many of the therapeutic claims made for Virol the Council considered grossly exaggerated; among them are the following:

". . . a complete food for children."

". . . a complete nutrient."

"The value of the Lime-Salts (representing the Egg Shells) contained in Virol is fully illustrated in its influence upon Rickets; whilst Struma, Chronic Bronchitis, Anaemia and Influenza are all combated by its use in a degree, which, we venture to say, has never been approached."

"The fat, as represented by the Marrow-bone and Egg Yolk, is so *minutely divided that it* admits of even far more rapid absorption by the *villi* of the intestine than milk."

"It is an ideal form of food, readily digested and assimilated in the weakest of conditions."

"Virol has a marked effect on the metabolism of the body, increasing the production of opsonins and stimulating phagocytosis. As an adjuvant *to the natural defensive processes of the patient in all diseases of bacterial origin* its value can scarcely be over-estimated."

The objections of the Council were transmitted to Virol, Ltd. The firm's reply was reported to the Council by the referee of the Committee on Therapeutics who held that no adequate or satisfactory answer had been made to the objections raised against the advertising claims for Virol.

The claims made for Virol being unsubstantiated and unwarranted, the Council voted that the preparation be refused recognition.

In accordance with the practice of the Council, the exploiters of Virol were afforded an opportunity to comment on the foregoing statement before its publication. On their objecting to the findings, the entire matter was turned over to a second referee. This referee, in making his report, reviewed the claims made for Virol and commented on the lack of evidence to substantiate these claims. He stated that a chemical analysis of the preparation had yielded the following result:

"Sugar, as maltose	60.0 per cent.
Fat	13.2 per cent.
Proteins	3.2 per cent.
Ash	1.6 per cent.
Water and volatile matter	21.6 per cent.

"There is no appreciable diastatic action. A little glycerol is present in the volatile matter. The preparation is therefore an extract of malt with fat and a small amount of protein."

He then continues:

"That Virol has food value cannot be denied, but that it has sufficient value to warrant the claims of the manufacturers is not evident. Virol cannot be considered a complete food, as the advertising literature reiterates, or an ideal food for infants. The amount of protein is far too low in comparison with the carbohydrates to warrant this view. The dosage recommended is not large. Thirty gm. a day would *furnish only* about 1 *gm. of protein* and 4 *gm.* of fat. The 3 teaspoonfuls a day recommended for children would furnish protein and fat even below this.

"If employed alone it cannot be a complete or sufficient food, and if employed along with other articles of diet—milk and bread, for example—it is not easy to see wherein lies the efficacy of the small weights of fat and protein added in the form of Virol. Here the demand made on our credulity is too great, as the protein in the preparation is the familiar protein of eggs, meat and malt, and the fat largely that from the egg-yolk and marrow, according to the claims. It is not known that any specific *virtues reside* in *these bodies,* or in the egg-shells, also claimed as present.

"In the opinion of the present referee there is nothing in the composition of Virol to justify the claims made for it. The judgment and recommendations of the first referee follow from the facts and must be accepted by the Council."

The Council directed that the previously prepared report be allowed to stand and that it be published along with a suitable reference to the report of the second referee.

Salesthyl and Sal-Hyl

Salesthyl and Sal-Hyl, two preparations exploited by the New York Salesthyl Corporation, were submitted to the Council for inclusion in New and Nonofficial Remedies. Salesthyl, a liquid, marketed in capsules, was stated to be the menthyl ester of methyl salicylate. Sal-Hyl was said to be an ointment of Salesthyl, and its exact composition was not disclosed.

The first preparation, Salesthyl, is claimed to have the ordinary therapeutic actions of salicylates in general. The specific advantages appertaining to this product however, according to the manufacturers, make it more efficient; for example, they say it is "free from toxic effects," "a resorbent of uric acid" a "bacterizer" with "never-failing results."

From either a chemical or a pharmacologic standpoint, it is difficult to understand how the menthyl ester of methyl salicylate could be at the same time more efficient and less toxic than methyl salicylate itself. As to the peculiar terms "bacterizer" and "resorbent of uric acid," the meaning of *which must* be *gessed at, the manufacturers have* submitted no evidence that their products possess these hitherto unknown virtues.

The claims as to non-toxicity and greater efficiency were supported in the advertising circular by tabulated reports said to have emanated from "well-known medical practitioners," who for the most part were asserted to be connected with New York hospitals. All of these reports were dated July, 1912. Investigation showed that these reports must have been written within two months after these "well-known practitioners" had graduated from a homeopathic school. This school claims no special experience with salicylates (in fact the use of salicylates in rheumatic conditions is not considered a homeopathic measure). The Council held it misleading to characterize these recent graduates as "well-known practitioners." The reports themselves, however, were insufficient and unconvincing and even contradicted the claimed superiority of Salesthyl.

The Council also objected to the name "Salesthyl" as likely to be confused with the well-established name "sal-ethyl," a salicyl ester described in New and Nonofficial Remedies.

The false claims having been brought to the attention of the present owners—the New York Salesthyl Corporation—*they explain that they obtained the reports among the assets* of their predecessors, the "American Salesthyl Corporation"; that they acted in good faith; that they will withdraw the pamphlets from circulation; and that they desire to make all needed reforms. In view of this the Council voted that Salesthyl and Sal-Hyl be refused recognition with the understanding that further consideration will be given the products when the needed reforms have been made and satisfactory evidence of the value of the products has been submitted.

Analutos and Analutos Tablets

Analutos and Analutos Tablets, 0.5 Gm. were submitted to the Council by a representative of the Royal Pharmaceutical Works of Meppel, Holland.

Analutos was stated to be the calcium salt of acetyl-salicylic acid. The advantages claimed over acetyl-salicylic acid itself are that Analutos is more soluble and less liable to produce gastric disturbance. The evidence submitted was not sufficient to show that Analutos has any advantages over acetyl-salicylic *acid,* or *that it* or its *properties* were discovered by the manufacturers. It is simply an unessential modification of a well-known substance, offered without evidence of superiority or originality. The Council held that physicians should not be burdened with a new, arbitrary name which does not even indicate the relation of the product to its well-known basic constituent. Accordingly it was voted that Analutos and Analutos Tablets be refused recognition.

Budwell's Emulsion of Cod-Liver Oil, Nos. 1 and 2

The Budwell Pharmacal Company, Lynchburg, Virginia, which markets these preparations, claims that "No. 1" contains cod-liver oil, "Iodide of Arsenic," "Iodide of Calcium," and "Iodide of Manganese." "No. 2" is said to contain in addition to the *ingredients* of *No. 1* creosote carbonate *and* guaiacol.

It is known that arsenous iodid is decomposed by contact with water. It is recognized that creosote carbonate is unstable and prone to liberate creosote. Iodide of manganese not being official, the supply on the market is not controlled in any way: tests of purity are not prescribed by the Pharmacopeia, the National Formulary, New and Nonofficial Remedies or other books of standards. Therefore doubt must be expressed as to the accuracy of the formulas as given. The

Council cannot accept such statements of composition without further evidence.

"No. 1" is commended for use in

"Chronic Rheumatism, Glandular Swellings, *later forms of Syphilis*, convalescence from Scarlet Fever, La Grippe and Malaria, Chronic Malarial Infection, Marasmus, Joint or other suppuration of standing, diseases of skin, chorea, anaemia, neurasthenia, obstinate neuralgia, scrofulous affections in general, and diarrhoea or dysentery (sub-acute or chronic) in childhood"

"No. 2" is said to be

"Prepared especially for the treatment of Chronic Throat, Nasal, Bronchial and Pulmonary Diseases."

In the advertising circular statements regarding the various ingredients of Budwell's Emulsion are quoted from obsolete text-books. These statements, for the most part, do not represent modern opinions on the subject. For instance, the circular praises the action of guaiacol as eliminated directly by the lungs, thus exerting a beneficial local effect and causing bacilli to diminish in numbers or to disappear. All of this is directly contradicted in authoritative modern publications on pharmacology, which hold that the excretion of guaiacol by the lungs is infinitesimal and its action on bacilli is nil. The Council held the preparations in conflict with its rules as follows:

1. Many of the therapeutic claims are exaggerations.
2. The method of exploitation amounts to an indirect invitation to the public to use these preparations as "consumption cures."
3. The preparations are unscientific, they constitute a reprehensible invitation to uncritical prescribing and their use is inimical to the best interests of the profession and the public. It is difficult to imagine in what conditions such a combination would be indicated. These preparations are a remnant of the days of polypharmacy. Their use is not in keeping with present medical thought and practice.

Citarin

Citarin, a product of the Farbenfabriken vorm. Friedr. Bayer and Co. (The Bayer Company, Inc., New York) admitted to N. N. R. in 1906, is discussed in New and Nonofficial Remedies, 1914, as follows: "This is one of the compounds which it is claimed increase the elimination of uric acid by forming very soluble compounds with that substance. Citarin is claimed to be useful for gout and chronic rheumatism." The referee of the Council in charge of formaldehyd derivatives reported that Citarin is recommended chiefly, if not solely, for increasing the solubility of uric acid in gouty conditions, this supposed effect being referred to the liberation of formaldehyd as Citarin is the sodium salt of an acid obtained by acting on citric acid with paraformaldehyd. The view that the solubility of uric acid could be increased by any such measures in the body has now been generally abandoned. For this reason the Council held that experience has failed to demonstrate the value of Citarin and directed its omission from the next edition of New and Nonofficial Remedies as a useless and unscientific product (Rule 10).

Past and Present in Biologic Investigation.—The sum and substance of biological inquiry may be embodied in two questions: What is the living organism, and how has it come to be? We often find it convenient to lay the emphasis on one or the other of these questions, but fundamentally they are inseparable. The existing animal bears the indelible impress of its past; the extinct animal can be comprehended only in the light of the present. For instance, the paleontologist is most directly concerned with problems of the past, but at every step he is confronted by phenomena only to be comprehended through the study of organisms as they now are. Our main causal analysis of evolution must be carried out by experimental studies on existing forms. All this seems self-evident, yet the singular fact is that only in more recent years have students of evolution taken its truth fully to heart. —Edmund B. Wilson, *Science*.

Correspondence

The Smegma Bacillus

To the Editor:—Your recent editorial (Jan. 23, 1915, p. 348) on the smegma bacillus does not cover all the facts. I have several times obtained from specimens of urine drawn by the catheter an acid-fast bacillus closely resembling the tubercle bacillus. On at least one occasion I have obtained the same bacillus from a hydronephrotic kidney that was certainly not tuberculous (*Am. Jour. Med. Sc.*, 1915, cxlix, 30).

Perhaps the precaution of previous urethral irrigation, as suggested by Young and Churchman, might have eliminated the acid-fast bacilli found in the bladder urine; but it could not have had the same effect on a specimen obtained by ureter catheter. That these were smegma bacilli I cannot assert. The important point is that they closely resembled the tubercle bacillus. The absence of tuberculosis was demonstrated by operation in the hydronephrotic case mentioned above, and in two cases in which the bacilli were *obtained by catheter from the bladder.* One was a gonorrheal pyelitis, the other a gonorrheal prostate.

In my hands the following method has proved a safe one for differentiation of these bacilli from real tubercle bacilli. The essential element is the prolonged immersion in alcohol, which appears to eliminate many bacteria that are acid- and alcohol-fast when stained briefly.

Gabbett's Method: After fixing, the smear is flooded with Ziehl's carbolfuchsin and heated to moderate steaming for six minutes. The slide is then washed in running water until no more carbolfuchsin comes away. *Without drying, the slide is then flooded with Gabbett's* methylene-blue solution for thirty seconds and again washed in water. If any acid-fast bacilli are found, the slide should be immersed in 95 per cent. alcohol for twenty-four hours and again examined. If the bacilli have retained their staining they are tubercle bacilli.

EDWARD L. KEYES, JR., M.D., New York.

Transplantation of the Anterior Temporal Artery

To the Editor:—My attention has just been called to the fact that Dr. George H. Monks of Boston has transplanted the anterior temporal artery with the flap attached to repair a defect made by excision of the lower eyelid for carcinoma. The description of his operation was published in the *Boston Medical and Surgical Journal*, Oct. 20, 1898. While there is considerable difference in some of the details of the operation, the principle is identical with that mentioned in my article on "Transplantation of the Anterior Temporal Artery" (THE JOURNAL, Jan. 30, 1915, p. 408). Of course, Dr. Monks is entitled to priority. I did not know of Dr. Monks' work when my paper was written.

J. SHELTON HORSLEY, M.D., Richmond, Va.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

INQUIRIES ABOUT THE HARRISON LAW

To the Editor:—In the issue of February 6 (THE JOURNAL, p. 518), in your editorial comments on the Harrison bill, and again in answering F. R. F., in this last issue (THE JOURNAL, Feb. 13, 1915, p. 611), you have asserted that physicians must keep a record of narcotic drugs dispensed. I have this day received from the collector of internal revenues for this district my registration blank and a copy of this law. Paragraph (a) of Sec. 2. says we must keep a record of these drugs, "except such as may be dispensed or distributed to a patient upon whom such physician, dentist or veterinary surgeon shall personally attend."

Art. 10. of the regulations says among other things, "A record, however, is required to be kept of all such drugs so dispensed or distributed (except such as may be dispensed or distributed to a patient, upon whom such physician, dentist or veterinary surgeon shall personally attend, i. e., personally visit)."

I might add that a local attorney advises me that no record would be required, according to the law, unless some one came into our office and made an explicit demand for one of these narcotics.

In view of these exceptions, just how much of a record is a dispensing physician supposed to keep?

C. C. Probert, M.D., West Branch, Mich.

Answer.—The statements in The Journal, referred to by our correspondent, were general provisions and were not intended to include the specific exemptions in the bill, which provide that drugs dispensed or distributed to a patient, on whom a physician shall personally attend, do not need to be recorded.

Article 10 of the regulations reads: "Under the exempting provisions of Section 2 of the act, no written order is required for the 'dispensing or distribution of any of the aforesaid drugs to a patient by a physician, dentist, or veterinary surgeon, registered under this act, in the course of his professional practice only.' A record, however, is required to be kept of all such drugs so dispensed or distributed (except such as may be dispensed or distributed to a patient, upon whom such physician, dentist, or veterinary surgeon shall personally attend . . . i. e., personally visit) and must show:

"1. The date when any such drug is dispensed or distributed;

"2. The kind and quantity dispensed or distributed in each case; and

"3. The name and residence of the patient to whom such drug was dispensed or distributed. . . .

"The record so kept must be preserved for a period of two years from the date of dispensing or distributing, and will be subject to inspection as provided in Section 5 of the act. Each physician, dentist and veterinary surgeon must supply himself with a suitable blank book for such record."

To the Editor:—I notice in last week's Journal your two comments on the new narcotic law. There is one point that you do not mention that should be made clear. If I understand the language of the law and the regulations, it exempts keeping a record of morphin and cocain and its preparations where it is dispensed directly to the patient. See Internal Revenue Regulation No. 35, page 5, line 4, and page 13, Article 10, line 6.

As I understand the language, if a physician sends the narcotic by the hand of another party, he has to keep a record. If he personally attends the patient a record is not necessary.

Is this your understanding? If not I should like to get it clear.

M. T. Clark, M.D., Temple, Okla.

Answer.—See the preceding answer. The regulations except drugs dispensed or distributed to a patient on whom the physician shall personally attend, that is, personally visit. Whether this applies only to drugs dispensed at the actual time of such a visit or to patients on whom the physician is at the time personally attending, would seem to be a matter for further interpretation.

To the Editor:—In re the Harrison bill, which goes into effect March 1, 1915, are there any provisions for border line towns? I am practicing on the state line between New York and Vermont. Do I have to make application to the deputy commissioner of internal revenue in New York as well as in Vermont for a registry number, and also to report to him?

E. F. Crofutt, M.D., Poultney, Vt.

Answer.—The law provides that every person affected shall register with the collector of internal revenue of the district, and that the office, or if none, then the residence of any person, shall be considered his place of business. No provision appears to be made regarding border line towns; nor would it seem to be necessary for any individual to register in more than one district. Article 1, paragraph 2 of the regulations reads, "If the applicant (other than a physician, dentist or veterinarian) has more than one place of business . . . a separate application for registry must be made." This would seem to imply that physicians were only required to register in a single district.

To the Editor:—Please send me the names of drugs which a doctor is barred from lawfully using, in case he does not pay the $1 revenue tax by March 1. C. S. Whitehead, M.D., Xenia, Ohio.

Answer.—"Opium or coca leaves or any compound, manufacture, salt, derivative, or preparation thereof."

LANDAU COLOR TEST FOR SYPHILIS

To the Editor:—In reference to the Landau color test for serodiagnosis of syphilis noted in The Journal, Oct. 10, 1914, p. 1317, the directions call for a 1 per cent. solution of iodin in methanetetrachlorid. What is the strength of the latter?

A. Judson Benedict, M.D., Newburgh, N. Y.

Answer.—Landau's original communication on this test was published in the *Wiener klinische Wochenschrift*, 1913, xxvi, 1702, under the title "Untersuchungen über eine Reaktion luetischer Sera mit einem Jodöl-Reagens." In this preliminary paper Landau described his test as follows, using as a reagent paraffin oil, to which was added tincture of iodin in the proportion of 5 drops of the tincture to 10 c.c. of the oil: To 0.2 c.c. of clear serum are added 2.5 c.c. of the reagent, and the mixture thoroughly shaken. The tubes are set aside in a dark place for from five to fifteen hours, when positive reactions will be shown in the perfectly clear decolorized mixture, while the negative reactions are indicated by a persistent yellowish-red coloration.

In his later work, we are informed, he uses a reagent containing more iodin, but employs less of the reagent, so that the end result is the addition of less iodin to the serum than in his first tests. His technic, as published in The Journal, as given above, is as follows: To 0.2 c.c. of the clear serum, add 0.01 c.c. of the reagent, consisting of a 1 per cent. solution of iodin in a solution of methanetetrachlorid of full strength (the latter is commonly known as carbon tetrachlorid, and is a colorless liquid somewhat resembling chloroform). Shake the mixture thoroughly until the iodin coloration has disappeared. Set aside for four or five hours at room temperature and examine. Positive reactions are indicated by a clear transparent yellow, while negative results are shown by an opaque whitish-gray mixture. These differences are not clearly distinguishable in all cases, so that one may test the mixtures for unbound iodin by the addition of a few drops of starch paste. As is well known, the presence of iodin is indicated by a blue coloration in the reaction with starch, so that negative tests will be shown by a blue color and positive tests by no change of color on the addition of the starch. This refinement is frequently necessary, as the variations in coloration and appearance of the serum are not always marked.

In using this test, as outlined above, experience has shown that only fresh serums are reliable, as has also been shown by Landau. The most reliable results are shown with serums not over ten hours old. The results with the test, fresh serums being used, parallel the Wassermann tests quite closely. This test would seem worthy of study, especially as a confirmatory test along with the Wassermann. It cannot, however, be relied on when used with serums sent to the laboratory from a distance.

PHENOL IN TETANUS

To the Editor:—In The Journal, Jan. 16, 1915, p. 278, you give an abstract of an article on "Phenol in Tetanus." I should like to ask if sixteen of the twenty-two patients did not die of phenol poisoning when they were receiving subcutaneously from 12 to 15 grains of phenol twice a day. Unless the patients suffering from tetanus by some unknown way can tolerate such doses of phenol without getting poisoned by it, it would seem pretty risky to try in every case of tetanus such heroic measures as described in this abstract. Likewise the dose of the chloral is enormous. I would appreciate your opinion in regard to the dosage of the phenol as given in the abstract. Is it safe or not to administer such a dose in tetanus?

K. H. Mallarian, M.D., Fargo, N. Dak.

Answer.—The doses of phenol given by Sainton in the article referred to do not approximate the fatal dose, which is as a minimum 15 gm. (½ ounce). It should be remembered that tetanus is an extremely fatal disease, and all forms of treatment employ heroic doses of the remedies used. The doses given by Sainton are about 50 per cent. above those recommended by Baccelli. Baccelli thinks that patients with tetanus are extremely tolerant to phenol.

The dose of chloral is considerably above doses which have proved fatal in exceptional cases, but the chloral in tetanus is probably largely counteracted by the convulsive condition of the patient. While the minimum fatal dose of chloral has been put at from 1.5 to 2 gm. (20 to 30 grains), much larger doses have been used in tetanus without serious results. In a case of tetanus, 93 gm. or 3 ounces were given in twenty-four hours without causing death. Anders recommends chloral to be given by rectal injections, 2.59 gm. or 40 grains, at a dose.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Connecticut: New Haven, March 8-9. Sec., Dr. Charles A. Tuttle, 196 York St., New Haven. Homeopathic: New Haven, March 9. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven. Eclectic: New Haven, March 9. Sec., Dr. T. S. Hodge, 19 Main St., Torrington.

Florida: Homeopathic: Jacksonville, March 5, Sec., Dr. C. W. Johnson, 33 E. Monroe St., Jacksonville.

Maine: Portland, March 9-10. Sec., Dr. F. W. Searle, 776 Congress Street.

Massachusetts: Boston, March 9-11. Sec., Dr. Walter P. Bowers, Room 501, No. 1 Beacon St., Boston.

Missouri: St. Louis, March 22-24. Sec., Dr. J. A. B. Adcock, State House, Jefferson City.

Rhode Island: Providence, April 1-2. Sec., Dr. Gardner T. Swarts, 315 State House, Providence.

Illinois October Report

Dr. C. St. Clair Drake, secretary of the Illinois State Board of Health, reports the written examination held at Chicago, Oct. 6-8, 1914. The total number of subjects examined in was 16; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 118; of whom 103 passed and 9 failed. Six candidates did not complete the examination. The following colleges were represented:

PASSED

College	Year Grad.	Total No. Licensed
Bennett Medical College	(1912,1) (1913,5) (1914,17)	23
Chicago College of Medicine and Surgery	(1909,1) (1910,1) (1911,2) (1912,1) (1913,3) (1914,28)	36.

Maryland Homeopathic December Report

Dr. O. N. Duvall, secretary of the Maryland Homeopathic Board of Medical Examiners, reports the written examination held at Baltimore, Dec. 14-15, 1914. The total number of subjects examined in was 8; total number of questions asked, 80; percentage required to pass, 75. One candidate, a graduate of Hahnemann Medical College and Hospital, Philadelphia, 1914, was examined and passed with a grade of 82.

Book Notices

Digest of Comments on the Pharmacopeia of the United States of America (Eighth Decennial Revision) and on the National Formulary (Third Revision) for the Year Ending Dec. 31, 1913. By Murray Galt Motter and Martin I. Wilbert. Paper. Pp. 518. Hygienic Laboratory Bulletin No. 98. Washington: Government Printing Office, 1914.

This, the ninth in the present series of digests, reflects a growing interest on the part of medical practitioners in official standards for drugs and preparations. The quotations and the references to medical journals appear to be more numerous than in previous numbers of the same series, and under the several headings "Biologic Products," "Enzymes," "Organo-Therapy," "Serums and Vaccines," "Biologic Methods and Tests," "Disinfectants" and "Clinical Tests," the active medical practitioner will find numerous and comprehensive references to literature on subjects of direct interest to him in his everyday work. Under the heading "A Limited Materia Medica" will be found a number of references which reflect the growing sentiment in favor of a thorough knowledge of the possibilities and limitations of a few drugs rather than a smattering of information on a great number of complex preparations regarding which no really authoritative data are to be had. Several pages are devoted to the enumeration of references concerning forms of administration and methods of administration, and in connection with a review on the general subject of alkaloids there will be found a table showing the influence of heat on solutions of alkaloids and their derivatives. The greater portion of the bulletin (366 pages) is devoted to a detailed review of the literature relating to the officially recognized drugs and preparations. Physiologic and therapeutic action and uses, toxic properties and the by-effects of drugs are referred to at length. The results of analyses in published reports of state food and drug officials, or officials entrusted with the enforcement of state food and drug laws, indicate that general conditions in the drug trade are as yet far from satisfactory, many of the more widely used drugs and preparations are frequently found to be of inferior quality, and the resolution adopted by the American Medical Association at its meeting in Minneapolis in 1913, urging on federal and state officials the need for more energetic and effective action in their efforts to eliminate drugs and preparations that are unreliable through carelessness, negligence, ignorance or other reasons, might well be again brought to the attention of federal and state officials for their consideration. Altogether it may be said that the bulletin reflects a fairly complete and comprehensive index of the literature relating to the origin, composition and uses of drugs and medicines, and is a contribution of value to efforts designed to bring about a broader and more comprehensive knowledge of the materials used as medicine. The volume should prove an incentive to the critical study of the possibilities and limitations of the available materia medica with the view of eliminating from the armamentarium of the physician all articles regarding the use or usefulness of which he may reasonably be in doubt.

The Science and Practice of Dental Surgery. Edited by Norman G. Bennett, M.A., M.B., B.C., Dental Surgeon to St. George's Hospital, with an Appendix on Dental Jurisprudence by P. B. Henderson, B.A. Cloth. Price, $9 net. Pp. 797, with 993 illustrations. New York: William Wood & Co., 1914.

This work is one of the most important English contributions to the literature of dentistry. It was evidently planned as a collaboration which should embrace the entire field of dentistry by English writers of note, who would present the most reliable views on the various subjects. Most of the contributors seem to have made extensive and impartial search for the more important facts developed by writers and investigators in the dental field. The editor, Mr. Bennett, has probably succeeded as well as any man could in his attempt to "impart unity of conception and style" to the writings of thirty-three other contributors. The one advantage in a compilation of this kind is that it represents the views of many men, often the opposing views of several men on the same subject. There is the objection, however, that in attempting to cover so large a field, general statements must too often stand without sufficient reports of investigation and induction. While this work presents in a single volume, in concise form, the more important facts, its greatest value would appear to be in the considerable number of well-selected bibliographic references which are appended to almost every chapter. References to these are given by number in the text, and this arrangement can hardly fail to lead the reader into a more extended study through the references. Only those writings which are referred to in the text are listed. In this feature, this work excels all other similar publications. The dental profession of America has cause to feel proud of the numerous references to American writings. It is also pleasant to note the general spirit of fairness in giving credit to men whose views are not in agreement. There are frequent references to German and French authors, showing the wide search which has been made in the preparation of the text. Like most books of this type, this work is not very well balanced, either in the space devoted to various subjects or in the relative prominence given them. More than one-fourth of the book, 209 pages, is concerned with the abnormalities of position of the teeth, while the etiology and pathology of dental caries has twenty-two pages, the diseases of the peridental membrane twenty-six pages, diseases of the dental pulp and alveolar abscess thirty-nine pages. Dental caries and the diseases of the peridental membrane, conditions which are most widespread and are causing the greatest destruction in the number of teeth lost, seem to be entitled to more extended consideration. In the elaborate discussion of irregularities we see the tendency of the specialist to make his field the hub instead of one of the spokes in the wheel. The illustrations have been collected from many sources, and most of them have been well chosen and faithfully reproduced.

The Diagnostics and Treatment of Tropical Diseases. By E. R. Stitt, A.B., Ph.G., M.D., Medical Director, U. S. Navy. Cloth. Price, $2 net. Pp. 421, with 86 illustrations. Philadelphia: P. Blakiston's Son & Co., 1914.

This book was at first intended as a laboratory guide; but, inasmuch as purely laboratory diagnosis of tropical diseases is impracticable, it has been extended into a reasonably complete, although concise, treatment of the infections usually included under the head of tropical diseases. The first part of the book is devoted to a clinical description of these diseases. The second is a laboratory guide for the examinations of the different morbid products from which the diagnosis must be made. The examinations are restricted mainly to those methods which are likely to be used in the examination of tropical patients. Altogether, the work appears to be concise without any loss of reliability. The illustrations are fairly numerous, and have been chosen evidently for their value as illustrating the subject. The book ought to be found useful not only by the student, but also by the practitioner. It must be remembered that in view of the wide latitude over which our country extends, and of its foreign possessions and the frequent migrations, no medical man is free from the liability of meeting a case of disease usually regarded as peculiar to the tropics.

A System of Operative Surgery. By Various Authors. Edited by F. F. Burghard, M.S., F.R.C.S., Lecturer on Surgery, King's College Hospital. Second edition. Five volumes. Cloth. Price, $30. New York: Oxford University Press, 1914.

Numerous advances made in surgery during recent years have necessitated a new rewritten and revised edition of this well-known British surgical work. Each of the five volumes takes up several fields of surgery, the various sections being written by different authors. On the whole, the system probably represents adequately modern English surgical opinion. As a general criticism might be stated the fact that in some portions the material is merely outline—a skeleton of the procedures. Each operative procedure is taken up under three headings: indications, operation and after-treatment, and in some places special difficulties and end-results are also considered separately. The work of American surgeons, as it has been published in American text-books and surgical periodicals, is frequently quoted. In Volume I are included general principles and technic, local analgesia, amputations, blood-vessel, nerve, muscle and tendon surgery, and the non-tuberculous affections of bones and joints. Volume II considers the tuberculous affections of bones and joints, harelip, cleft palate, cancer of the face and lips, surgery of the jaws, esophagus, tongue and stomach, and includes a good article on hernia. There is a conspicuous absence of the padding so often found in composite works. Volume III takes up the operations on the ductless glands, bile passages, and pancreas of the central nervous system, genito-urinary organs, and the thorax and its contents. In Volume IV the intricate operations of the ear and sinuses are elaborately portrayed, and in Volume V gynecologic operations are considered in a manner probably not better given elsewhere. The authorities who have combined to make this exceedingly valuable work include such men as Legg, Stiles, Moynihan, Mayo-Robson, Godlee, Bland-Sutton, Jellett and others. The work is beautifully illustrated throughout, and the editing of Burghard has made this set a finished and admirable work.

The Pocket Formulary for the Treatment of Disease in Children. By Ludwig Freyberger, J.P., M.D., M.R.C.P. Fourth edition, with an Appendix on Poisons, Their Symptoms and Treatment. Leather. Price, $2. Pp. 260. New York: Rebman Company, 1914.

We are told that this formulary has been out of print for some time, although this is the fourth edition, revised and enlarged. The question is at once raised in one's mind whether the continuance of such formularies is desirable. It is to be hoped that the day of complicated formulas containing five active ingredients is practically past. On the other hand, a knowledge of how to employ simple remedies ought surely to be one of the conditions for the license to practice medicine. If we remove these two features, the book is reduced to a list of remedies with their properties, dosage, etc., which would occupy considerably less space, and would be helpful in emergencies to the average practitioner. Some features of the book are very commendable. The drugs with which the author has had personal experience in the treatment of diseases of children are spoken of "as very useful" or "as useful" in the paragraph devoted to therapeutics; those as to the usefulness of which he had to rely on the experience of other physicians, the author has said are "recommended" for the treatment of certain diseases. This distinction between personal experience and hearsay evidence might be profitably made by other teachers on therapeutics. The appendix contains a number of useful features, such as preparations suitable for baths, gargles, hypodermic injections, inhalations, sprays, etc. Von Pirquet's and other cutaneous tests for tuberculosis are described, as well as an outline of tuberculin treatment. Unusual with an English book, it contains no proprietaries.

Meatless Cookery. With Special Reference to Diet for Heart Disease, Blood-Pressure and Auto-Intoxication. Compiled by Maria McIlvaine Gillmore. Introduction by Louis Faugeres Bishop, M.D., Clinical Professor of Heart and Circulatory Diseases, Fordham University. Cloth. Price, $2 net. Pp. 352. New York: E. P. Dutton & Co., 1914.

This book contains a complete series of attractive menus and recipes selected apparently with reference to their uses in cases of heart disease, blood pressure and "auto-intoxication." It is these diseases, the author believes, in which rich foods are especially offensive, and she places foods among the main causes of the neuroses and various intoxications consequent on the present day mode of living. The book not only is the outcome of her own experience in hospital cooking, but also contains the suggestions of patients and various experts consulted. The recipes are wholesome, nutritious, and not of the delicate type or fancy order usually found in meatless cook books. A few recipes for the use of chicken and egg are added in case heavier diets may be required.

Medicolegal

Effect of Contracts with Physicians to Furnish Medicines and Attend the Poor

(Johnson vs. Hamilton County (Ia.), 149 N. W. R. 639)

The Supreme Court of Iowa affirms a judgment in favor of the county, which was sued for $111.10 for medicines and medical supplies furnished an indigent person on the verbal order of the trustees. The court holds that the fact that physicians were employed to furnish medical attendance, medicines, etc., for the poor during the entire time of this account was, under the statutes and prior decisions, decisive of the question, and that the trustees could not ignore such employment. It has been held that the liability of the defendant must be fixed by the statute, or it does not exist, and that, when the board of supervisors have employed physicians to render medical aid and furnish medicines for the poor of the county, the trustees cannot disregard such employment by the employment of some other persons to furnish such medicines, and thereby render the county liable. It was conceded on the trial that these physicians did not give a bond, as required by the statute, and it was claimed by the plaintiff that there was no evidence that the contracts were let under competitive bidding to the lowest bidder. However, it has been recently held that, notwithstanding such fact, the contracts are not invalid, but are binding and in force. The bond required is to secure the faithful performance of the contract. The court thinks this bond is for the purpose of protecting the county in the event of failure of the contracting physician to perform the contract, and is not to protect the person furnishing medicines. It was said that one of the physicians was insolvent and unable to furnish the medicine. But the evidence did not show that any demand was ever made on him to furnish such medicines. The plaintiff furnished the medicines and supplies on the order of the trustees, when, at the same time, the county had a contract with physicians to furnish them. The trustees might not ignore the contract. Without now deciding the point, the court may say there might be a case of emergency, where the county physician is not accessible, when the trustees might employ a physician. To do so would open the door to abuses.

Proof of Mental Feelings Just Prior to Accident—Popularity of Physician

(Sanders vs. Boston & Maine Railroad (N. H.), 92 Atl. R. 546)

The Supreme Court of New Hampshire affirms a judgment for $15,000 damages in favor of the plaintiff, a physician, who was injured by a collision of one of the defendant's trains with a carriage in which he was riding. The court says that the plaintiff was asked on direct examination what his feelings were when he saw the train about to smash into his carriage. He answered: "My first thought was—when I saw I could not escape in spite of my efforts, the horrible thought flashed into my mind, 'My wife and daughter!' just the instant before I went unconscious, and after I tried my best to escape and found it impossible." It could not be said that the plaintiff's method of describing his mental suffering was improper, nor that the testimony was incompetent in substance. If the negligence of the defendant caused the plaintiff mental suffering preceding the injury, he was entitled to compensation therefor. It was therefore competent for the plaintiff to describe his mental feeling just as the accident took place, and the words he used to do so indicated that he thought he would be separated from his wife and daughter in an instant by death, to him a horrible thought, giving him great anguish of mind. The testimony described the special mental suffering that the plaintiff experienced at the time of the collision and was competent. The cases cited by the defendant, in which evidence of mental suffering was excluded, were mostly those where plaintiffs experienced such suffering after the injury, in contemplating their own condition, or the difficult position in which their families were placed, and were not like the case at bar. Nor was counsel's statement to the jury that the plaintiff was a popular man improper. Any argument, warranted by the evidence, that bears on the question of damages, is legitimate. The plaintiff's popularity as a man affected his earning capacity, and was therefore material. It was intimated by the defendant that it would have been legitimate to have argued that the plaintiff was a popular physician, if there had been evidence of it. Unquestionably that would have been so, and a stronger argument; but it does not follow that it was not also competent to state that the plaintiff was a popular man. Such a man has many friends, and, if engaged in a profession, attracts business. Popularity is one of the elements of success. It is a matter of common knowledge that many professional men of very mediocre ability and attainments do a large and lucrative business by reason of their popularity; and there is no doubt that much of their business comes to them, not by virtue of the professional standing, but because they are popular men in the community. The defendant cited many cases to show that character evidence is not admissible on the question of damages. This is true, except in cases where character is directly in issue. But here the court is not considering evidence and argument bearing on the character of the plaintiff, whether he was a normal man, but concerning a distinguishing trait or characteristic of the man, affecting his earning capacity.

Law Governing Conspiring of Inmate of Insane Asylum to Escape

(Drew vs. Thaw (U. S.), 35 Sup. Ct. R. 137)

The Supreme Court of the United States reverses an order discharging Thaw on habeas corpus while held in New Hampshire on a warrant from the governor for his extradition to New York, where he was indicted for having conspired with certain persons to procure his escape from the Matteawan State Hospital for the Insane, and having escaped, to the obstruction of justice and of the due administration of the laws. The court says that it was suggested that it was not a crime for a man confined in an insane asylum to walk out if he could, and that therefore a conspiracy to do it could not stand in any worse case. But that depends on the statute. If the acts conspired for tend to obstruct the due administration of the laws, the New York statute makes the conspiracy criminal whether the acts themselves are so or not. The court does not regard it as open to debate that the withdrawal, by connivance, of a man from an insane asylum, to which he had been committed as Thaw was, did tend to obstruct the due administration of the law. At least, the New York courts may so decide. Therefore the indictment charged a crime. The most serious argument on behalf of Thaw was that if he was insane when he contrived his escape, he could not be guilty of crime, while if he was not insane, he was entitled to be discharged; and that his confinement and other facts scattered through the record required the court to assume that he was insane. But this was not Thaw's trial. Even if it be true that the argument stated offered a nice question, it was a question as to the law of New York which the New York courts must decide. The statute that declares an act done by a lunatic not a crime adds that a person is not excused from criminal liability except on proof that at the time "he was laboring under such defect of reason as: 1, not to know the nature and quality of the act he was doing; or 2, not to know that the act was wrong." The inmates of lunatic asylums are largely governed, it has been remarked, by appeal to the same motives that govern other men, and it well might be that a man who was insane and dangerous, nevertheless in many directions understood the nature and quality of his acts as well, and was as open to be affected by the motives of the criminal law as anybody else. How far such considerations shall be taken into account it is for the New York courts to decide, as it is for a New York jury to determine whether, at the moment of the conspiracy, Thaw was insane in such sense as they may be instructed would make the fact a defense.

Society Proceedings

NORTH SIDE BRANCH OF THE CHICAGO MEDICAL SOCIETY

Meeting held Jan. 15, 1915

The President, Dr. F. A. Jefferson, in the Chair

Trifacial Neuralgia and Its Treatment

Dr. Hugh T. Patrick: The striking characteristic which distinguishes trifacial neuralgia from almost all other pains about the head and face is the brevity of the pain. Another strongly diagnostic characteristic is that the pain may be started by slight peripheral irritations about the face, by eating, talking, drinking, brushing the teeth, washing the face, and so forth. It is a very rare case in which one cannot start the pain by taking a wisp of cotton and making a light wipe over the face. Another peculiarity about the starting of the pain is that an irritation in the distribution of one of the three branches of the trifacial may start the pain in another branch. I have called these areas from which pain may easily be started "trigger zones." There is no known definite cause of trifacial neuralgia. I am certain that arteriosclerosis and degenerative changes are not causative, and that it is not caused by anything like auto-intoxication, but I could not prove the latter statement. I have never found Bright's disease, diabetes, alcoholism or metallic poisoning to have any particular influence on the condition. Local infections and irritations in the area of the fifth nerve may have something to do in originating the disease. The proportion of my cases which gave a history of or had at the time of examination sinus disease or pyorrhea or a bad tooth, suppurating at the root, etc., is rather high, but I have never known a case to be cured by the removal of the teeth. Trifacial neuralgia is a distinct clinic entity. The pathology is unknown. Some think it is due to changes in the cells of the gasserian ganglion, but there is nothing to support that opinion. The prognosis is bad.

Medicinal treatment is not altogether ineffective. I have known of very good effects from heroic doses of aconitin, but this has to be given with care. The castor oil treatment is sometimes effective, but not often. Some cases have been treated by attending to anomalies of the eyes; some by taking spurs off the septum and pieces off the turbinates, but these treatments are always without permanent effect, in my experience. Really, the treatment of trifacial neuralgia is operative. The best operation, of course, is the radical removal of the gasserian ganglion, or section of the sensory root between the ganglion and pons, which is equally effective. But this is a very serious and difficult operation, and requires a refined technic. Even in the hands of some good general surgeons, the mortality runs as high as 10 per cent. and over. In the hands of experts it is not over 1 per cent. That, however, is the only operation that can be depended on to cure. A number of peripheral operations have been advocated, including the Abbé—section of the nerves at the base of the skull, with interposition of some substance to prevent the ends of the nerve from uniting, which is generally futile, but probably the best of the peripheral methods. It, too, is a difficult operation to perform. Some men advocate division of the nerves in the jaw, or at their exit, and pulling out as much as possible, but after nearly all these operations, the nerves regenerate and the pain returns.

There are several methods of alcohol injections for the treatment of trifacial neuralgia, that of Schlösser and that of Haertel, but, for the greater part, I have followed the method of Lévy and Baudouin, in which a straight needle is used, the point of entrance being at the lower border of the zygoma, relatively far forward for the middle branch, and farther back for the inferior branch. Injection of the first branch is done at the supra-orbital notch with a long hypodermic needle. Lately I have been using a very slender iridoplatinum needle, as advised by Brissaud and Sicard. With this needle the puncture is less painful, and penetration much easier, but once introduced, the needle is much less easily manipulated than the heavier one. All methods are uncertain as regards the accuracy with which the operator can put the needle into the nerve, and this uncertainty is the greatest objection to this treatment. When the injection is properly done, the dangers are practically nil. I have heard of one case in which a very considerable slough followed the injection, but I have never heard of a fatality. In accordance with the uncertainty of reaching the nerve, the results may be said to be exceedingly variable. If injection is made accurately into the nerve, the patient always has relief for at least a year, and in many cases for three or four years. If the alcohol is placed only alongside the nerve, the relief is short-lived. My own opinion is that young persons with this disease should have the radical operation done by one of the few surgeons with extensive experience with this operation. Old persons or those with some grave physical disease would better have the alcohol injections, because by this means, without risk, they may be kept comfortable as long as they live.

DISCUSSION

Dr. F. B. Moorehead: There are two or three things I wish to emphasize: first, the percentage of cases due to lesions in or about the jaws. I have never seen a case of trifacial neuralgia that was due to a demonstrable lesion of any sort. I have seen cases in which one tooth after another was removed, after each extraction there seeming to be a cessation of the pain, only to return again. I have never seen a case that gave any improvement whatever from the removal even of unerupted teeth, when it was a case of typical classic trifacial neuralgia. I have done a number of peripheral operations, some of which have done some good, and a number did not do very much good. The peripheral operation is absolutely to be condemned, because at most there will be a short period of relief from pain, and the chances are that when it recurs it will be worse than before, because in regenerated nerves there seems to be more irritability than before the nerve was excised. It is possible to do an operation which is exceedingly simple on the third branch, which I believe at present gives splendid hope of good results, and that is, with an incision not over an inch in length, made just at the shadow line in the region of the facial artery. One can easily go through transversely, find the canal in the lower jaw, and then it is a simple matter to work forward until the mental foramen is reached; then work back as far as possible and lift the nerve out of its bed completely. Then by avulsion the peripheral branch is removed. Then, by taking an instrument devised for the purpose, you can go backward and remove the entire nerve from the bony structure. If any of the nerve is left in the canal, it will be certain to regenerate, but with this simple operation thoroughly performed, it is possible to remove the third branch from the jaw completely. But when all is said and done, and the treatment of trifacial neuralgia is reviewed, alcohol injection is the best because it is simple, is not accompanied by any danger to the patient, can be done in the office, and is not especially painful.

Recent Methods of Treating Syphilis of the Nervous System

Dr. Harold N. Moyer: So far as one can judge at this time, neosalvarsan is far less dangerous than salvarsan, but not to be compared with it in efficacy. It was natural that the inefficiency of salvarsan in nervous syphilis should have led to investigations which resulted in the introduction of salvarsanized serum into the spinal theca. The intraspinal method in its various modifications can be credited with results not heretofore obtained in the use of salvarsan in nervous syphilis. Presumably the active constituent of salvarsan is arsenic, which is of known value in malarial and trypanosome infections, a class of organisms to which the *Treponema pallidum* belongs. As a means of introducing arsenic into the system it is inferior to older methods; it involves far more discomfort, and its dangers are by no means slight. I began experimenting with arsenic in the late eighties, and was early impressed with the fact that this substance is stored in the liver in larger quantity than in any other organ. It occurred to me that it would be therapeutically more efficient if introduced under the skin, to be absorbed by the general circulation, and in this way its effect on the nervous system would be greater. I have now used arsenic in the treatment of nervous syphilis for ten or twelve years, associated with the ordinary mercurial treatment, and have found this combination very effective. I use the arsenic in the form of sodium arsenate, which I believe to be the most valuable form of arsenic for the treatment of syphilis of the nervous system. Next comes salvarsan, in my opinion, and the least valuable form is sodium cacodylate. My first injections into the spine were given for the purpose of overcoming tabetic crises and pains, particularly the latter, and I used sodium cacodylate at that time, about eight or nine years ago. Later I changed to sodium arsenate injections into the spinal canal, and so far as I know without the slightest untoward result in any case. Some men, I believe, now inject small quantities of salvarsan into the spinal canal. I see no advantage in this, and I cannot see that the results are any better than those I get from the injection of sodium arsenate into the spinal canal. However, I have not injected it into the spinal canal for several years. Not that I would hesitate to do it in appropriate cases, but I believe practically the same results can be obtained by the persistent use of arsenic under the skin. I am an enthusiastic believer in the arsenic treatment of nervous syphilis as an adjuvant and associated with the mercurial treatment, with the occasional use of iodids. I do not believe in the value of salvarsan as compared with other forms of arsenic, particularly sodium arsenate, and for that reason do not use it in syphilis of the nervous system.

DISCUSSION

Dr. George W. Hall: Like Dr. Moyer, I am rather an enthusiast over the use of arsenic, but, unlike him, I am a strong adherent to the use of neosalvarsan in the treatment of syphilis. My work has been more especially along the line of intraspinal injections. I have made about fifty such injections of neosalvarsan, both in private work and at the Cook County Hospital. We withdraw from 16 to 18 c.c. of spinal fluid if possible. We never make an injection of 3 or more milligrams without the use of 16 c.c. of spinal fluid as the vehicle. I think unfortunate results have been due to the use of more concentrated solutions. We use freshly boiled distilled water as a solvent for the neosalvarsan in such dilution that 1 minim contains the required dose. We began this form of medication about a year ago, and in some instances have obtained very good results—whether permanent or not, I am not willing to say. In the meningitic cases we get better results than in the cases of arterial involvement of the central nervous system. In the early tabes cases we have had apparently good results by reduction of pain. Of course, the cases should be chosen carefully for intraspinal medication, just as we choose them for other methods of treatment. Men who are especially addicted to the use of alcohol should not be subjected to this treatment. Also, there is a good deal in the method of injection used. Sometimes the injection is made too high, and fluid is reinjected perhaps too rapidly. Sometimes it comes in contact with the nerves at the end of the cord in too concentrated solution, and in that way produces the bad results which we occasionally see reported. In other instances slight inflection follows the injection. Care should also be taken that the fluid injected should be near the body temperature—neither hot nor cold. In cases of general paresis I believe the intraspinal injections are of no importance whatever. Once in a while, however, we meet patients who have an idiosyncrasy toward this form of medication—either intraspinally or intravenously. The kidneys must be watched when neosalvarsan is used intravenously. We should not expect permanent results after two or three injections any more than we should expect to cure malaria with three doses of quinin. We should not stop at the third or fourth injection, but give five, or seven, or even eight injections, if necessary, if the patient can stand it, and along with these injections continue with the other treatment outlined, at the same time making occasional examinations of the spinal fluid, Wassermann tests, etc.

Dr. Hugh T. Patrick: We should be a little cautious in giving these injections, and watch the knee jerks all the time. If they weaken, the injections should be stopped at once. It is possible to produce a typical arsenical multiple neuritis. Recently I have been having a most distressing experience from the results of intravenous injections of neosalvarsan in the form of a marked dermatitis, which is exceedingly rare.

Dr. Harold N. Moyer: One must realize, when dealing with arsenic—whether in the form of salvarsan, neosalvarsan or the sodium arsenate—that he is dealing with a dangerous and toxic remedy. Many cases of arsenical neuritis following the use of Fowler's solution have come under my observation. The reason I have not found it necessary to use the injections into the spinal canal is that with the persistent, insistent, steady use of sodium arsenate I can apparently get enough absorbed by giving it under the skin. You must be persistent in the treatment, whether with neosalvarsan or sodium arsenate, but that also can be overdone. Go as far as the remedy will be tolerated. After reading the literature, and reviewing my own experience, my judgment is that salvarsan is a form of arsenical medication. If I am wrong, then this whole thesis falls. If I am right, then I believe my form of arsenical medication is better than salvarsan, more manageable, more efficient, and safer.

1. **Nearthrosis or Arthroplasty.**—Before operating for the relief of an ankylosis, Tubby says, it is requisite to ascertain if the cause which has given rise to ankylosis is in abeyance at the time of the suggested operation, and if it has been in abeyance for some years. More particularly does this apply to tuberculosis. Old foci may be opened up, or they may be so extensive as to prevent reformation of the ends of the bones in the way desired. Tubby cites seven cases and expresses himself as being far from optimistic with regard to the future of nearthrosis by the interposition methods. In his cases in which some success was attained, cargile membrane or chromicized peritoneum was used. It seems to him that muscular fibers or fibers composed of fascia and adipose tissue; or failing them, chromicized cargile membrane or pig's bladder, are the best material so far in use. He further says that he had noted, if the extensor tendon be partly divided at the time of operation, the patient suffered little or no pain.

4. **Silk Ligaments at Ankle in Infantile Paralysis.**—Of seventy-nine operations performed by six operators on sixty-eight patients, fifty-one were periosteal insertions, and twenty, bone, while in eight it was not stated whether the bone or periosteal method was used. Of forty-four periosteal operations in which the result could be verified, 30 per cent. (13 cases) were successful; 20 per cent. (9 cases) were partially successful; 50 per cent. (22 cases) were failures. Of seventeen bone drill operations in which the result could be verified, 70 per cent. (12 cases) were successful; 12 per cent. (2 cases) were partially successful; 17 per cent. (3 cases) were failures. Lovett's belief, from the examination of these cases and from a study of their records combined with his clinical experience, is that the silk ligament operation in cases of dropped ankle from infantile paralysis is a useful operation attended by a good proportion of success; that a most rigid technic is necessary, and that the especial preparation of silk used is not what determines the outcome; that prolonged fixation and support are necessary, because the silk is not strong enough of itself to hold up the foot, but serves as the core of a ligament which is the real supporting structure.

6. **Surgical Treatment of Poliomyelitis Anterior.**—The more or less widespread tendency to perform ankylosing operations in poliomyelitis anterior is deprecated by Nathan. This applies particularly to the knee and shoulder joints. Whatever may be the case so far as the shoulder is concerned, he cannot see why a patient who wears a brace with a snap joint at the knee, is not better off than one with a perfectly stiff knee. He urges that the operative treatment of poliomyelitis anterior depends on and should be planned according to definite mechanical principles. It is not sufficient that the muscle whose tendon is to be transferred is physiologically intact; it must approximate in power (which can readily be determined), the force which it is to balance or overcome. The course must correspond, mathematically, with the direction in which the force to be transferred is to act, and the site of the implantation must be such that the greatest possible leverage may be obtained. Finally, in computing the resultant of the muscular forces, one should also more carefully consider the increased power to be gained by shifting the relative positions of the bones which make up the articulations, thus rearranging the lever arms and, in consequence, the balancing forces.

12. **Phenol Injection Treatment of Infected Joints.**—Cone has treated three cases of hydrops articuli with phenol followed by alcohol. The first case treated in 1904 had both knees involved. In this case he used 5 drops of pure phenol followed by 10 drops of alcohol. The patient, an old man, left the hospital in three weeks, all the effusion having disappeared. The last patient was treated in March, 1914; she had hydrops articuli of the right knee, and psoriasis. In this case Cone injected 10 drops of 5 per cent. phenol, followed by alcohol and in two weeks the swelling had disappeared. Of ten cases of gonorrheal joints with little pus formation and in which the diplococci were demonstrated, all were benefited; in two the pain was relieved after the first injection (5 per cent. phenol followed by alcohol), no further injection being required. In the other two or three injections were made before complete relief was afforded.

In five cases in which there was considerable distention of the joint, operation was required before complete relief was given. One of these recovered with a movable joint, walking five weeks after operation. In one case a staphylococcus infection of the elbow, referred after all palliative measures had been used with no relief of swelling or pain, one injection of 5 per cent. phenol followed by alcohol relieved the pain at once and in three days all swelling had disappeared, the patient going to work in a week. In three cases of villous arthritis there were no good results.

One patient with tuberculosis of the knee joint, in which tubercle bacilli were demonstrated, was using his knee with protection three months after two injections of 5 per cent. phenol and alcohol. He reported three years later perfectly well. One patient with an old tuberculous knee with dislocated patella, received two injections and three months later was not complaining of stiffness or swelling of the joint. Two cases of tuberculosis of the knee which were injected required subsequent incision but healed nicely three months after simple incision and drainage. In two cases, one streptococcal the other staphylococcal arthritis of the knee, they injected three times before very extensive operation, with prompt healing. One case of congenital syphilis of the knee joints in a boy of 16 years was not improved by the injections, but got well at once after one injection of ¼ grain of mercury biniodid in oil. Other cases of syphilis proved unresponsive to the phenol. In a case of obstinate sacroiliac joint trouble the injection of 5 drops of pure phenol followed by alcohol relieved the symptoms in a few weeks by locking the joint. This ankylosis was demonstrated a year later by roentgenogram. From the results of treatment by this method it would seem that the method is most reliable in all cases in which there has been no disorganization of the joint and the case is treated before extensive pus formation.

13. **Effect of Pituitary Extract on Secretion of Cerebrospinal Fluid.**—Extracts of the posterior lobe of the hypophysis introduced intravenously by Weed and Cushing served to discharge cerebrospinal fluid from a calibrated catheter introduced in its pathway (ventricle or subarachnoid cistern). Positive responses occurred to the injection of nearly all the fluid proprietary preparations, though in the authors' hands the desiccated extracts have proved to be the more active. The possible increment to the fluid through increased permeability of the cerebral capillaries and drainage out along the perivascular lymphatics was excluded in most of their experiments by the method of tapping the fluid pathway in the third ventricle rather than in the cisterna magna. The response occurred under most variable conditions and appeared to be independent of respiratory influences or hemodynamic reactions, for it may coincide with periods of respiratory cessation or acceleration or with periods of arterial hypertension or depression. A prolonged flow from the ventricle may continue even after death and may reach an amount apparently in excess of the normal content of the ventricles. That there is an actual increase in the amount of fluid secretion was shown by its non-recession into the cannula following periods of increased cerebral vascularity, as well as by the measurement of the amounts discharged. The evidence inclines Weed and Cushing to believe that the outflow under the circumstances of their experiments represents an actual secretory response rather than an expulsion of preformed fluid due to physical conditions resulting in changes in the volume of the brain. Hence their conclusion may be justified that: Extracts of the posterior lobe of the hypophysis increase the rate of production of cerebrospinal fluid (choroidorrhea) by stimulating the secretory activity of the choroid plexuses.

14. **Blood Pressure During Vomiting.**—According to Brooks and Luckhardt their experimental studies showed that vomiting is accompanied by marked changes in the circulatory system and interference with respiration. There is seen, sometimes, a period of elevated pressure, more frequently a *sudden and enormous drop in blood pressure with cardiac* inhibition at the moment of emesis, always periods of great oscillations in the blood pressure. These great and sudden oscillations of the blood pressure may cause a rupture of the blood vessels which would occur with the same pressure but with slower changes. The faint feeling accompanying emesis may be the result of the cerebral anemia occasioned by the cardio-inhibition and resulting drop in blood pressure.

15. **Effect of Thyroid Extract on Blood Pressure.**—The authors' experiments have been begun with an attempt to isolate from a watery extract of the fresh gland, all of the substances which can be separated, with as little alteration as possible of their chemical structure. These include the so-called nucleoproteins, globulins, coagulable and noncoagulable albumins, and the alcohol soluble and alcohol insoluble residue. Each of these bodies have been dissolved and injected intravenously in dogs, and the results on the blood pressure, respiration and heart action noted in the usual kymograph tracings. The solution of the alcohol soluble residue left after removal of all other substances has been found to be the only substance which produces any appreciable effect on the blood pressure. The glands used throughout these experiments have been pig thyroids. It was found that iodin is present in all the fractions of the extract. The coagulable fractions which are the richest of all the fractions in iodin, produce little or no depressor effect even in relatively enormous dosage. The "residue," or fraction of the extract which remains after the removal of the coagulable fractions, contains iodin, but in smaller quantity than the other fractions. The depressor effect of the "residue" bears no relation to the total iodin content of the gland from which the residue is derived. The depressor effect of the "residue," follows only after its intravenous injection. It is not manifested after subcutaneous injection. Tachycardia is not regularly produced by this depressor substance, although a very large dose (10 c.c.) does accelerate the pulse rate at the lowest points of blood pressure. Later, the force and rate of the heart beat return to normal with the return to normal of the blood pressure. The active portion of the "residue" is not precipitated by basic lead acetate; is not altered by boiling nor by passage through a Berkefeld filter; and is soluble in alcohol. No immunity to the depressor effect of the "residue" or of its active portion was noted during the limit of the experiment (from four to six hours).

16. **Influence of Oxalates, Citrate and Tartrates on Isolated Heart.**—The results obtained by Salant and Hecht show that sodium tartrate is much less active than citrate or oxalate. Equimolecular solutions of the latter, perfused for the same length of time, indicate that sodium citrate may be more toxic than oxalate.

18. **Sensibility of Gastric Mucosa.**—According to Carlson and Braafladt the normal gastric mucosa is devoid of pain and tactile sensibility, but protopathic temperature sensibility is present. Chemical (and possibly mechanical) stimulation of nerve endings in the normal gastric mucosa gives rise to a sensation identical with appetite. The stomach mucosa may be said to be provided with a protopathic appetite sense. The stimulation of the gastric mucosa does not contribute to the sensations of hunger and of fulness. Stimulation of the gastric mucosa increases the reflex excitability of the spinal cord, and induces changes in vasomotor tonus. The latter appears to be dependent on conscious cerebral processes induced by the gastric stimulation.

20. **Hunger Contractions in Stomach of Rabbit.**—During starvation of the rabbit, Rogers states, the stomach activities are augmented and the reflexes acting on the gastric motor mechanism are different from those of normal digestion peristalsis. There are no sharp dividing lines, however, between the normal peristaltic contractions occurring during digestion and those occurring during hunger. It would thus seem that, in the rabbit at least, the gastric hunger contractions are intensified digestive peristalses. The empty stomach of the rabbit shows very strong and rapidly repeated contractions and marked tonus variations. In the hungry rabbit *there is a state of increased tonus in the stomach musculature*. Tonus changes are more marked and occur more frequently during hunger than during normal digestion peristalsis. The contractions of the stomach occurring during hunger in the rabbit are not inhibited by the sight, smell, taste or chewing of food. The contractions occurring during hunger are inhibited or weakened by the introduction into the stomach of small quantities of water, weak acids, alcohol or sugar solution. Normal peristalsis is not inhibited by the same amounts of these solutions. Excitement (central nervous influences) inhibits the stomach contractions and causes a lowering of the tonus of the stomach musculature.

21. **Reflexes from Intestinal Mucosa to Stomach.**—Brunemeier and Carlson found that gastric juice, chyme, acids, alkalies, water, milk and oil introduced into the small intestine inhibit gastric hunger contractions and gastric tonus for varying periods. This inhibition of these gastric hunger contractions and tonus is due partly to mechanical, partly to chemical stimulation of the intestinal mucosa. The chemical stimulation produces the greater effect. This inhibition of gastric hunger contractions apparently take place primarily by the "long" or central reflex path, but "short" or local reflex paths in Auerbach's plexus are also involved.

23. **Vasomotor Nerves of Duodenum.**—Burton-Opitz concludes that the blood vessels of the duodenum are innervated by nerves which ascend from the celiac ganglion by way of the plexus gastroduodenalis and plexus pancreaticoduodenalis.

25. **Pregnancy and Pancreatic Hyperglycemia.**—Total extirpation of the pancreas in non-pregnant dogs by Carlson and Ginsburg resulted in the onset of pancreatic diabetes within from seven to twelve hours. Complete pancreatectomy *in pregnant bitches near term was not followed by hyperglycemia* and glycosuria, etc., so long as the fetuses were alive and the placental connections were not severed. At the onset of labor the blood sugar began to rise, so that the hyperglycemia with consequent glycosuria, characteristic of pancreatic as well as severe clinical diabetes was established on the completion of the delivery. This absence of diabetes, the authors state, may be due either to a secretion from the fetal pancreas reaching the maternal blood, or to some detoxicating action on the part of the fetal pancreas.

44 Recent Investigations in Relation to Infectious Diseases in South America. R. P. Strong, Boston.

43. **Ameba from Normal Human Intestine.**—From Curet's study it appears to be well established, that free-living ameba and ameba cultivated from the healthy intestine cannot produce typical amebic lesions in the gastro-intestinal canal or the liver of susceptible animals when introduced in pure cultures or with favorable bacterial symbiosis. When either one or several species of ameba were fed to animals or injected into their rectum with bacterial associations, the results were negative unless the symbiotic microorganism was capable of producing an intestinal upset. When pure cultures were used no results were obtained. Suspensions of one or many species of ameba, either in pure culture or associated with some microorganism, when injected into the liver of animals, failed to show lesions when the bacteria were omitted or were not pathogenic. Positive results were obtained only when the bacterium in symbiosis was pathogenic to the host. In every instance, the lesions when present did not suggest amebic invasion. Negative results followed when the ameba and their symbionts were injected into the liver of an animal previously immunized against the bacterium, although lesions followed the injection of the same ameba with the same symbiont in an animal not protected against the symbiotic organism. Control animals that were fed or injected with the various bacteria used as symbionts, without the ameba, developed the same symptoms, died as frequently and the lesions were similar to those in which the ameba were injected with the special microorganism.

45. **Children with Positive Skin Tuberculin Reactions.**—Rogers says that, before the age of 2, a positive skin reaction seems to be an indication that the child's life is likely to be short. The mortality among all children, up to the age of 10, who react to the von Pirquet test is much higher than that of normal children.

48. **Roentgen-Ray Examination Following Operation for Pyloric Tumor.**—Three authentic cases are referred to by Scudder in which the pylorus tumor discovered at operation has been seen from three to nine months following a plastic operation. These facts taken with the postoperative Roentgen-ray findings in twenty-six cases recorded, the author believes, afford a reasonable basis for the conclusion that the pyloric tumor persists and does not tend to disappear. The recognition of the persistence of the tumor in congenital pyloric stenosis is important. Scudder says that the tumor alone with the mucous membrane changes is an adequate cause of the obstruction in all its phases, and it is unnecessary to imagine a pyloric spasm associated with the obstructing tumor. The surgical treatment of these cases is, without question, the permanently effective treatment. The postponement of the operation with the idea, now so prevalent, that the hypothetic spasm will let up and the tumor disappear and the child recover is unjustifiable. A baby having tumor obstruction will always have tumor obstruction. The omission of the hypothetic pyloric spasm from any consideration in these cases will result in earlier adequate surgical relief.

73. **Folin-Farmer Method for Estimation of Nitrogen.**—Analysis by Bock and Benedict of some seventy samples of urine by the Folin-Farmer colorimetric method showed that this method usually agrees with the Kjeldahl method within about 2 or 3 per cent. For the most part the figures by the Folin-Farmer method were appreciably lower than by the Kjeldahl process, but variations occurred between + 4 per cent. and — 11.8 per cent. of the total quantity of nitrogen present. Therefore the Folin-Farmer method is not to be regarded as equivalent to the ordinary Kjeldahl procedure in accuracy or reliability. Two modifications of the Folin-Farmer method are presented, one of which is recommended as of service in blood analysis or in cases in which only small quantities of material are available. The results reported show that the Folin-Farmer method can be employed with advantage in any instances in which the total quantity of nitrogen present is very small (as in the determination of the total non-protein nitrogen of the blood), because a high percentage error is of much less importance in such analyses.

74. **Estimation of Sugar in Blood.**—The red color obtained by heating a dextrose solution with picric acid and sodium carbonate is employed as the basis of the method proposed by Lewis and Benedict for the determination of blood sugar. The blood protein is removed by precipitation with picric acid. The method of blood sugar determination is as follows: Two c.c. of blood are aspirated through a hypodermic needle and piece of rubber tubing into an Ostwald pipet, a little powdered potassium oxalate in the tip of the pipet preventing clotting. The blood is drawn up a little above the mark and the end of the pipet is closed by the finger. After the rubber tubing and needle are disconnected, the blood is allowed to flow back to the mark and is discharged at once into a 25 c.c. volumetric flask containing 5 c.c. of water. The contents of the flask are shaken to insure thorough mixing and the consequent hemolysis of the blood. Then 15 c.c. of saturated aqueous solution of picric acid are added, as

well as a drop or two of alcohol to dispel any foam, and the contents of the flask are made up to the mark with water and then shaken. After filtration 8 c.c. aliquots are measured out into large Jena test tubes for duplicate determinations. Two c.c. of saturated picric acid solution and exactly 1 c.c. of 10 per cent. sodium carbonate are added (as well as two glass beads and 2 or 3 drops of mineral oil), and the contents of the flask are evaporated rapidly over a direct flame until precipitation occurs. About 3 c.c. of water are added, the tube is again heated to boiling to dissolve the precipitate, the contents of the tube are transferred quantitatively to a 10 c.c. volumetric flask, cooled, made up to the mark, shaken, and then filtered through cotton into the colorimeter chamber. The color is compared at once with that obtained from 0.64 mgm. of dextrose, 5 c.c. of saturated picric acid, and 1 c.c. of 10 per cent. sodium carbonate, when evaporated to precipitation over a free flame and diluted to 10 c.c. The calculation of the sugar present in the unknown blood sample is very simple. The original 2 c.c. of blood were diluted to 25 c.c. and of this amount 8 c.c. were taken for a determination. In other words, the aliquot contained the equivalent of $8/25 \times 2$ c.c., or 0.64 c.c. of blood.

79. **Colloidal Silver with Lecithin, in Treatment of Tumors.**—The experiments described by Rohdenburg were negative.

80. **Bacteria Cultivated from Human Cadaver.**—Canavan and Southard present the results of a second series of 100 bacterial cultivations from a heart's blood and the cerebrospinal fluid post mortem in cases of mental disease. The bacteria were cultivated on agar plates inoculated with 1.5 c.c. heart's blood and others with 1.5 c.c. cerebrospinal fluid. Of the blood cultures, 44 per cent. remained sterile. Of the cerebrospinal fluid cultures, 24 per cent. remained sterile. Cocci prevailed and there were more cultivations of cocci from the cerebrospinal fluid than from the blood.

81. **Protective Value of Aqueous Extract.**—The possibility of leukocytes containing neutralizing substances within the meaning of immunity, Youland says, is remote. Leukocyte extract apparently exerts its action on animal infections only in the border line type of infection, and is without curative value in more constant conditions.

82. **Therapeutic Use of Aqueous Extract.**—The negative results Williams and Youland have obtained from the use of leukocyte extract as regards its action on the temperature, the leukocyte count, the condition of the patient, and on the course and termination of the disease, offer little hope of any appreciable therapeutic results from the use of this agent in lobar pneumonia.

84. **Reaction of Cow's Milk Modified for Infant Feeding.**—The addition of alkalis to modified milk for the purpose of neutralizing "the high acidity of cows' milk," Clark says, is based on wrong principles. The addition of alkalis to modified milk for the purpose of preventing firm clots in the infant stomach, is a procedure which not only may be unnecessary, but one which involves a possible inhibition of both gastric proteolysis and lipolysis. Finally, the addition of alkalis to modified milk is criticized because of its probable influence in displacing from the intestine a normal bacterial fermentation and replacing it with those proteolytic or "putrefactive" processes which are responsible for many of the digestive disorders of infancy.

85. **Streptococci Isolated from Milk-Borne Epidemics of Tonsillitis.**—The streptococci causing epidemics of tonsillitis, according to Smith and Brown, are not necessarily the same in different epidemics either in the same or different localities. The success likely to attend the tracing of such epidemics to their source will depend on a minute, detailed study of individual strains of streptococci and the discovery of certain minor distinguishing characteristics as guides. The streptococci which have been the agents of recent outbreaks are all alike in that the colonies produce, immediately around them, a clear hemolyzed area on blood agar plates (horse blood). They differ from the common throat coccus, in which the colony has a partly discolored and hemolyzed mantle between it and an outer, narrow, clearer zone. There is, at present, no satisfactory evidence that bovine streptococci associated with mastitis or garget are the agents of tonsillitis in man. Whenever cases of garget are suspected as sources of infection in man, both human and bovine types should be looked for.

99. **Danger of Delay in Diagnosis and Treatment of Intussusception in Infancy.**—The following points are emphasized by Peterson. 1. Intussusception in infancy presents a rather uniform and characteristic picture and should be recognized without difficulty. 2. Aerohydrostatic and mechanical measures can succeed in but a limited number of cases. Such treatment is not without danger. 3. Early laparotomy, with manual reduction of the invagination, is the safest, the simplest, and the most successful method of treatment.

110. **Emetin in Pyorrhea Alveolaris.**—Further observations have led Bass and Johns to consider one hypodermic of ½ grain of emetin given every few days after the first course of several doses, as recommended in their former paper, to be of comparatively little value. If it is necessary to repeat the emetin it should be given for at least three days, as at first. The only indication for repeating the emetin treatment is the presence of ameba, which can best be determined by proper microscopic examination. The fact that it is sometimes necessary to make and examine several preparations from a lesion before ameba are found shows that even this method may be misleading, especially when negative. The authors emphasize the fact that the emetin destroys the ameba by some specific action, but that, after the ameba have been destroyed, the lesions remain, and will require a variable length of time to heal, according to the extent and character of the lesion, and other influences. The pocket is usually extensive and contains necrotic and, often, tough tissue (especially periosteum in the bottom), and more or less carious bone. For nature to liquefy and remove this material will necessarily require a considerable length of time, during which there must continue to be more or less pus formation. As long as the lesion is not healed up it naturally offers favorable soil for reinfection.

Bass and Johns have experimented considerably with fluidextract of ipecac as a local application made by the patient for the purpose of preventing reinfection, and have learned that not only will it theoretically prevent reinfection, but it will actually destroy the ameba present in many early lesions. The proper method of using it seems to be to brush the teeth in the usual way to clean, and then to apply one drop of fluidextract of ipecac to the wet rush and brush again forcing some of the solution between the teeth and spitting out the excess, but do not wash it out. They advise that all persons now free from the disease should use this specific, either in this form or possibly in some other form, as a prophylactic instead of the many commercial preparations now in use.

115. **Active Immunization of Hay-Fever.**—Oppenheimer and Gottlieb endeavored to immunize patients by injecting gradually increased doses of pollen extract to produce tolerance to the anaphylatoxin formed in the body. Beginning with from 1 to 5 units of pollen extract, the dose was gradually increased until a local reaction appeared at the site of the injection. This dose was then continued until the patient showed no more reaction. Then the dose was gradually increased as before. One unit of pollen toxin is the amount of antigen dissolved in 1 c.c. of extract at a dilution of from 1 to 20 millions. Eleven patients were treated in 1914, before and during the season for autumnal catarrh. Six patients were treated in advance of the attack. One of these was cured for the season, four exhibited very mild symptoms, and one was not improved. Five were treated during the attack. The symptoms in four subsided after receiving from one to four injections, whereas one patient received no benefit. Altogether there were five cures for the season. In four cases there was marked improvement In two cases there was no improvement. Of the two cases that were not improved, one patient had a polypoidal degeneration of the middle turbinate with underlying bone necrosis.

The other reacted to both ragweed and golden rod pollen. He received in all thirty-three injections, alternating the ragweed extract and the golden rod extract. He came very irregularly. It is possible that at times the treatment was too intensive. His physical condition was so poor that possibly a tolerance could not develop. Nine patients reacted to ragweed pollen and two reacted to that of both ragweed and golden rod. Both of these received both golden rod and ragweed antigen hypodermically. One was cured, but the other was not improved. The authors describe in detail their method for obtaining the pollen. It is extremely cumbersome and Oppenheimer and Gottlieb are now working on a less laborious method.

142. **Value of Typhoid Vaccines in Typhoid.**—The curative use of typhoid vaccines in the course of typhoid in order to stimulate further antibody formation, according to Krumbhaar and Richardson, has a logical theoretic basis, although its mode of action has not as yet been demonstrated experimentally. Practical proof of its value is afforded by the rise in agglutinin curves after such vaccination. The proper use of vaccines in the treatment of typhoid has been found in over 1,800 cases cited by various clinicians to be without harm, and usually to be followed by beneficial results. The 93 cases reported by the authors support this view. The best results are obtained if the injections are begun early in the disease, especially before the tenth day. Late in the course of the disease, except in selected cases, the value of

vaccine (both theoretically and practically) is more dubious. In the chronic complications of typhoid, such as periostitis and cholecystitis, other investigators have obtained good results from vaccines. The contra-indications against vaccine treatment of typhoid are not yet clear. The authors hesitate to advocate their use in moribund or very toxic cases, during hemorrhages or suspected perforations, or in such complications as pneumonia or otitis in cases in which other organisms are involved.

The best dosage has also not been determined. Semple, Petrowitch, Watters and Eaton have had good results with small doses; MacArthur, Fletcher, Meakins and Foster equally good results with much larger doses. While this would indicate to some that the true benefit lay elsewhere, Krumbhaar and Richardson feel that the discordance is due to differences of patients and epidemics, preparation of vaccines, and "personal factors." The dosage must vary within certain limits for each patient and no cut and dried rule should be attempted. The more severe the infection, the smaller and more cautious must be the dosage. With their methods of preparation, they felt that the best initial dose for the average adult was 500 million; if this proved to be the proper amount, two or more larger doses were given usually at three-day intervals.

145. **Appendicitis.**—Since only eight out of about 700 patients seen by Lichty under all conditions and circumstances died, he believes that the disease need not be considered with such alarm. He adds, however, that an early operation during the first acute attack is not only safest but will likely prevent a life of more or less chronic invalidism. He advises that a careful routine study of the leukocytes in acute appendicitis is of diagnostic value, and a routine study of the gastric secretion in chronic appendicitis yields valuable information. The end results in cases of chronic appendicitis are often unsatisfactory and can not be definitely foretold.

3. **Cases of Inoperable Cancer Treated with Goat Serum.**—In 1890 a patient, aged 60, suffering from inoperable cancer of the uterus was treated by Wilson with goat serum. Six ounces of serum were injected into the basilic vein. The serum reaction was severe. The uterus healed in about six weeks and the disease was apparently cured. She lived two years and died of an acute disease. Five other cases are cited by Wilson suggesting that the goat serum relieves pain by attacking the outskirts of the advancing growths, retarding or preventing their advance into normal and sensitive tissues. A sufficiency of the same chemical action ought to lead to shriveling up of the tumor, and did so in some instances.

10. **Black (Pigmented) Appendix.**—Two cases of marked pigmentation of the appendix met with in women of different ages and circumstances are cited by Battle making a series of six cases seen by him and which present some common features. In the first place there was an extensive brownish-black pigmentation evidently not limited to the appendix but spreading an unknown distance into the large bowel. The patients were all females (aged 27, 30, 32, 43, 48 and 48) and in each there was a history of constipation of long standing, which amounted to intestinal stasis in more than one of them according to their attendants. It would appear as if in some the difficulty with the bowels had led to a secondary inflammatory affection of the appendix. Operation in each was for the relief of pain caused by this. The pigmentation was found on examination of the removed appendix, and in only one was there any appearance of darkening of the bowel as examined from the operation incision. Microscopic examination showed the deposit to be both in and between the cells of the mucous membrane.

Chemical analysis of the first three specimens showed that the pigmentation was produced by a deposit of iron, the exact combination not being defined owing to the small quantity of material available. There was no bismuth, lead, or mercury present. In only one patient was there any history of the taking of iron in medicine, and she had been given the compound syrup of the hypophosphites. As to the source of iron, Battle says, there can be very little doubt that it is derived from wheat flour prepared by the iron rollers which are used in the modern process of milling. Chemical examination of a quantity of best flour has shown the presence of an abnormal amount of iron, although none could be separated from the flour by means of a magnet. The question of the influence of roller milling in the causation of appendicitis is one which has interested Battle for some years. Facts are accumulating to show that it is a serious factor.

11. **Salicylate Therapy in Rheumatic Infection.**—That salicylate has the power of diminishing the activity of the rheumatic infecting agent, Miller says, may be taken as the working basis of salicylate therapy in rheumatism, and the drug should be administered with the sole view of controlling the bacterial activity. Of this the temperature chart is as accurate an index in rheumatic as in other infections (namely, tuberculosis). Care must be taken to discriminate between symptoms directly due to active rheumatic inflammatory processes and those dependent on toxic parenchymatous changes which may remain long after all bacterial activity is at an end. The temperature chart is the guide to the dose of salicylate to be employed. Used solely with a view to controlling bacterial activity; the effective range of dosage for child or adult is usually from 60 to 120 grains per diem. Less than 1 dram daily is rarely sufficient; more than 2 drams need seldom be given. Much larger doses than these have been shown to be safe if properly administered, and if necessary to gain control, may be used, but for the most part "massive" doses have been administered in cases of chorea in which there was no evidence of bacterial activity remaining.

Any dose greater than 100 grains daily should be given subdivided into 10 doses in the twenty-four hours. Large infrequent doses should never be given, particularly in children. Constipation must be avoided. The sodium salicylate should be combined with an equal dose of sodium bicarbonate;

Miller has not found the double quantity of soda necessary in doses of this grade. Vomiting in cases of severe cardiac dilatation may be difficult or impossible to prevent, but in other cases may be avoided for the most part. The more serious symptoms of salicylate poisoning (acid intoxication) should nowadays never be allowed to arise.

Quarterly Journal of Medicine, London

18 *Dyspnea and Its Relation to Blood Reaction (Acidosis). T. Lewis and J. Barcroft.
19 *Congenital Myotonia; Thomsen's Disease. W. Johnson and G. Marshall.
20 Rationale or Modus Operandi of Wassermann Reaction and Abderhalden's Test. J. E. R. McDonagh.
21 Metabolism of Nitrogen in Dermatoses. H. L. Tidy.
22 Salvarsan Treatment of Congenital Syphilis. L. Findlay and M. E. Robertson.

18. **Dyspnea and Its Relation to Blood Reaction.**—The following is a synopsis of the cases reported by Lewis and Barcroft. 1. Dyspnea in a man who presented signs of renal and myocardial affections. Nocturnal attacks. Acidosis was found on two occasions. 2. A case of cardiovascular affection. Dyspnea on exertion and nocturnal angina pectoris. Acidosis found. 3. A case of arteriosclerosis and renal affection in a woman who exhibited breathlessness. Nocturnal attacks and Cheyne-Stokes breathing present. Acidosis found. 4. A case of cardiorenal affection in an old woman. Cheyne-Stokes breathing and dyspnea prominent. 5. Aortic disease and aneurysm, cardiac failure, renal involvement. Dyspnea, often intensified for short periods, was a chief feature of the case. Cheyne-Stokes breathing was found. 6. A case of aortic disease, cardiac failure and renal involvement. Dyspnea, Cheyne-Stokes breathing, nocturnal intensification of breathlessness, prominent. Terminal pneumonia present. 7. Cardiac failure of rheumatic or specific origin, in a man who exhibited mitral stenosis and aortic disease. Dyspnea present. No acidosis. 8. A case of mitral stenosis with auricular fibrillation and cardiac failure. No acidosis found. 9. Cardiac failure in a patient who exhibited mitral stenosis. Dyspnea present, but no acidosis. 10. Pregnancy in a patient suffering from rheumatic heart disease. Breathlessness accompanied by acidosis. 11. A case of large white kidney, with dropsy of renal type, complicated by aortic disease and slight mitral stenosis. Urgent breathlessness in the absence of cyanosis was a feature of the case. Acidosis was discovered. 12. Pneumothorax giving rise to acute illness in a dormant case of pulmonary tuberculosis. Dyspnea accounted for, partially at all events by acidosis. 13. A case of exophthalmic goiter, complicated by maniacal symptoms, persistent vomiting, and distress of breathing in a young man. Acidosis was found. Death from exhaustion. 14. A case of acute pneumonia in a young man, ending in recovery. On the fourth day acidosis was found. The crisis occurred on the eighth day; acidosis though of lesser degree, was present on the tenth day; during convalescence the blood reaction was normal. 15. A case of severe acute pneumonia in a young man, terminating fatally. Profound acidosis was discovered on the tenth day of illness. 16. A case of acute pneumonia, ending fatally, in an elderly woman. Acidosis was found on two occasions during the course of the illness. The CO_2 tension in exposed air was low. 17. A case of acute lobar pneumonia in an otherwise healthy young man; ending in recovery. Acidosis was found. 18. Paroxysmal breathlessness in a man who had signs of cardiac and renal involvement with aortic aneurysm. Exaggerated acidosis found during the attack.

19. **Congenital Myotonia; Thomsen's Disease.**—Of a family of eight children examined by Johnson and Marshall, four were found to be affected with Thomsen's disease. It was possible to investigate three of these carefully. They found the physical signs of the nervous system were normal; that the muscles in all three cases were larger than normal, but the actual strength of contraction and ability to maintain that contraction for any length of time were below normal. The myotonic contraction did not occur in reflex action. The duration of the local contraction produced in a muscle by mechanical stimulation varied with the degree of force used by the percussing finger. In one case, dyspnea was easily provoked by any exertion, and this patient took an anesthetic very badly. Also, in one case the authors carried out a histologic investigation of the muscle and compared it with muscle removed from a normal living control. They find that in Thomsen's disease the muscle fibers are larger than normal, their diameter being about twice the normal size. This increase was entirely the result of increase in the number of fibrillae in each fiber. The nuclei were in proportion to the size of the fibers, that is to say, there was no relative increase. Some of the nuclei occupied a position in the substance of the sarcoplasm. The longitudinal and transverse striation of the fibers showed no variation from the normal.

In another case a series of myographic tracings were taken. There was no definite alteration in the contractions whether taken in the morning or in the evening after a day's activity. Complete immobilization of a limb for twelve hours produced exaggeration of the condition in the muscles so rested. After numerous repetitions of a movement, the action became more brisk, but the patient was always twice as slow as a normal control. Reinforcement quickened up the first movement of a series at the expense of the later ones, thus conforming to the reaction met with in the normal subject. Alterations in temperature produced no registerable effect. Ischemia and congestion both caused lengthening of the contraction. Electrical stimulation by electrodes applied to the skin showed that weak stimuli produced brisk contractions, and strong ones a prolonged spasm. With the patient anesthetized they were able to stimulate the median nerve, directly with weak faradism. Momentary stimuli produced a contraction which persisted for fifteen seconds and prolonged stimulation a contraction which lasted only eight seconds. After two hypodermic injections of strychnin the muscular movements became practically normal. Johnson and Marshall suggest the use of strychnin in the treatment of this disease.

28 *The Ultraviolet Rays in Treatment of Freezing Injuries. (Action des rayons de courtes longueurs d'ondes sur les membres congelés.) J. Pougnet.

28. **Ultraviolet Rays in Treatment of Frozen Members.**—Pougnet has applied to human tissues the discovery that the ultraviolet rays revive frost-bitten plant buds. He exposed the frozen limb for three or four minutes every two hours to the rays from a quartz mercury lamp, with a current of 110 volts and 4 amperes, the distance 25 cm. No appreciable benefit was observed with simple freezing, but when the freezing was accompanied with ulceration the effect was quite marked, healing commencing by the third to fifth day. In one case in which both feet had been frozen and were swollen, blistered and painful, the pain was arrested by the ninth or tenth sitting and the swelling subsided the sixth day. He adds that many soldiers are being sent back from the front now with badly swollen feet, and he hopes that this treatment will thus be given a thorough trial.

29 *Treatment of Typhoid. E. de Massary and E. Weil.
30 Adjustable Aluminum Splints. (Attelles en aluminum pour fractures et plus spécialement pour fractures compliquées.) Marion.

29. **Treatment of Typhoid.**—De Massary's experience has convinced him that the constant application of an ice bag to the abdomen answers all the purposes of cold baths, while it leaves the patient in peace. He gives a number of case his-

tories to illustrate his method and its advantages. Except for cleansing purposes, he thinks repeated baths in typhoid are not only useless but harmful. To keep the patient absolutely quiet and supply fluids in abundance are the main indications, supplemented by the continuous chilling of the abdomen. For this he covers the abdomen with a thick layer of talcum powder and over this a thin flannel. On this is placed a large bag of ice, not filled full, as its weight must not be heavy nor even enough to cause discomfort. The air is carefully expelled from the ice bag, so it will be limp and fit to the surface below. The whole is kept in place with a folded sheet; a bandage is apt to roll up and slip. If the skin shows purple anywhere, the ice should be suspended for a few hours. He has been using this treatment for years and has had but one eschar, and then it was only superficial. The bag does not need filling oftener than every two and a half hours.

The patient is encouraged to drink often so he gets up finally to 4 or 5 liters, including 2 or 3 liters of boiled milk flavored with coffee, tea or alcohol. After each cup, the patient rinses his mouth with an alkaline fluid and swallows a mouthful. Tea and other infusions flavored with alcohol in some form make up the copious intake of fluids. This keeps the salivary glands and kidneys working and thus wards off parotitis and other complications. The injury from lack of fluids is shown in the cases of soldiers sent back from the front with typhoid. They are unable to get much to drink on the journey, and suppurative parotitis developed in three such cases recently in his service. He has the tongue, gums and pharynx cleaned regularly with a mixture of equal parts of glycerin and Vichy water, and a few drops of camphorated oil are placed in each nostril. He keeps up the refrigeration of the abdomen until the temperature has been normal for two days. He declares that it is the best possible means to combat the ulcerative enteritis of typhoid, while it acts also on the septicemia by chilling the blood. Experiments have shown that the blood is chilled in this way as effectually as when the ice bag is applied to the heart region. His mortality in forty-six cases in three years has been 4.3 per cent. Among the soldiers, received mostly under unfavorable conditions, the mortality has been higher, bringing the total up to 8.5 per cent. of 140 cases.

48. **Physicians and the War.**—Kirchner compares the work and achievements of the medical corps now with those of former wars, declaring that such a comparison shows better than anything else the vast progress made in recent years in the medical sciences. The latest achievement is the systematic effort from the very first to treat the wounded in such a way that the crippling thereafter will be the least possible. Preservation of the earning capacity is in the mind of the surgeon tending each wounded man, and this principle is carried through in the convalescent homes, orthopedic institutions and training schools later. The specialization in practice previous to the war brought hardships at first, as certain specialists were comparatively helpless outside of their particular field. The appointment of consultants in internal medicine, etc., soon remedied this, but the experiences during this war, he thinks, will tend to impress on physicians the advantage of all-around training instead of intense specialization.

51. **Differential Diagnosis of Sepsis and Acute Leukemia.**—In the case reported, a man of 29 suddenly developed fever, chills and pains in the chest and abdomen. In the course of three weeks the symptoms partially subsided, but the headache persisted, with a temperature of 39.4 C. and pulse 128; leukocytes 4,000; but no edema nor enlargement of glands. Finally the gums began to bleed; a necrotic patch developed and the blood count then showed only 400 leukocytes. The temperature rose, while the red cells dropped to 1,700,000, and the man died in less than six weeks from the first symptoms. Necropsy showed intense proliferation of myeloblasts, although they had not poured out into the circulating blood. No bacteria were found in the blood or organs, not even in the necrotic patch in the gums.

52. **Pneumonia After Contusion.**—The claim for an indemnity was based on the development of fatal pneumonia soon after a contusion of the right chest. The pneumonic process was localized mainly in the left lung. The exhumed cadaver showed that the left lung had long been bound down by adhesions and its functioning was thus much impaired, and it was not equal to the task thrown on it by the accident to the other side of the chest, breaking the ribs and causing the man to spare that lung as much as possible. The experts therefore agreed that in all probability the pneumonia would not have developed if the trauma had not occurred.

53. **Vaccination Against Chicken-Pox.**—Kling points out several minor points in technic which may explain Handrick's failure in his attempts to stamp out varicella in an institution by vaccination (mentioned in these columns January 16, p. 284). Kling's success in this line he ascribes to the large number of inoculations made, always six or seven, and to the use of the lancet in making the scratches instead of injecting the virus with a needle. In Kling's service 73 per cent. of 108 children not vaccinated developed varicella, while only 23 developed it among the 135 vaccinated, and in all but 10 the eruption was restricted to the vicinity of the vaccination field.

55. **Slight Changes Evident in the Heart on Return from the Seat of War.**—Levy comments on the great change in the hospitals at Berlin from the cases of patients formerly encountered, most of them with chronic diseases, to the present patients, the hosts of vigorous young men. Even in these strong and sturdy bodies, however, he frequently encountered symptoms such as are observed only with slight

mitral insufficiency, with or without a slight tendency to stenosis. It is possible that in some of them there may have been an old slight spark of valvular disease which was fanned alight by the physical exertions of the campaign, but he thinks this explanation can apply to only a small proportion. Brugsch suggests that these heart changes are of infectious nature, which assumption would explain also the polyneuritis or fever sometimes observed with them, but Levy objects to this in that even with the mildest infectious endocarditis the course is not so free from complications as in the cases he is discussing. The most plausible explanation is that the heart is simply suffering from the continuous physical overexertion from the marching without adequate periods for rest and sleep. This overexertion kept up for weeks and months, when the troops are all the time on the march, exhausts the men, so that in some the nervous system becomes unstable and, like children, they respond with fever to slight causes.

56. **Abnormal Elimination of Calcium in Children's Urine.**—Kleinschmidt remarks that children sometimes have a milky, turbid urine with a white sediment consisting of calcium carbonate and phosphate. The total elimination of calcium, however, is not increased, as the usual proportion in the stools is lower to balance the increase in the urine. The pellicle that forms on such urine suggests that colloids in the urine cause the turbidity. Adults sometimes have as much calcium sediment in the urine, but the urine is not turbid. The metabolic findings and the appearance and subsidence of the calcium salts in the urine in two typical cases described in detail, testify to the fact that the phosphaturia is of nervous origin. The children presenting this condition are always those with unstable nervous systems, usually an inherited neuropathic taint. Restless sleep or sleeplessness, headache, pallor, sweats, pruritus, abdominal pain, diarrhea and hysteric or epileptic attacks are common. The most convincing proof of the nervous origin of the calcariuria is the prompt way in which it subsides, as a rule, after change of scene, while dieting, etc., may not influence it at all.

57. **Familial Ataxia and Myxedema.**—Rothmann relates that a girl of 15 had curvature of the spine, ataxia and talipes cavus. The father and three sisters are normal but a brother of 18 has myxedema and talipes cavus and never grew taller after the age of 10. The mother developed myxedema after the menopause. The history of this family seems to indicate that there must be some connection between the defective functioning of the thyroid, causing the myxedema and the dwarf growth, and the hypoplasia of the central nervous system responsible for the Friedreich's ataxia—all of which are manifestations of perverted functioning in the internal secretion system. The combination of acromegaly and syringomyelia, cases of which Petren has published, confirm this connection between certain affections of the nervous system and the internal secretions. Rothmann treated the mother and son mentioned above with thyroid tablets, and the myxedema retrogressed considerably, while the son grew 2 cm. in height in six weeks, down appeared in the axillae, the childish treble voice became deeper, and he lost nearly 4 kgm. of his proportional excessive weight. This benefit under thyroid treatment confirms the assumption that ascribes the dwarf growth and infantilism to hypothyroidism. The girl with ataxia was given the thyroid treatment, too, but no positive benefit was apparent.

59. **Artificial Pneumothorax in a Diabetic.**—A man of 55 had had mild diabetes for seventeen years, and during the last year signs of progressive pulmonary tuberculosis appeared, with albumin in the urine. He became very weak and, as a last resort, an artificial pneumothorax was induced on one side although there were evidently foci in both lungs. As the gas was injected it was evident that there were adhesions between the sheets of the pleura, but these stretched or tore under the positive pressure of the gas so that the pneumothorax could be properly concluded and maintained. Marked improvement followed; the fever subsided, the albumin was only 0.1 per thousand and sugar only 0.7 per cent. and the diazo reaction became negative. Bossart adds that in all but three of his forty-seven cases requiring artificial pneumothorax, the gas had to be injected under considerable positive pressure. He does not think there is much danger of air embolism even when there are tough connective tissue adhesions. They resist the pressure from the gas while there is no danger with the purely fibrinous adhesions which tear at once.

62. **Treatment of Bone and Joint Tuberculosis.**—This entire number of the *Corr.-Blatt* is devoted to the discussion of this subject which took place at the annual meeting of the Swiss Surgical Association a few months ago. Rollier of Leysin reported his results with what he calls helio-alpine treatment applied in 2,000 cases of tuberculous processes in bones and joints in the last ten years. He declares that, with his method, bone and joint tuberculosis of all forms and degrees and at all ages can be cured. His leading principles are that these lesions, as well as visceral and glandular tuberculosis, are not a local process but a general disease, and that the skin is an organ for absorption as well as for other functions. Exposure to the sunlight has thus a microbicidal action, but also an oxidizing, a reducing and an analgesic action while it promotes the development of fibrous tissue and modifies the medium. With Pott's disease, keeping the patient lying prone develops the muscles of the chest, back and trunk throughout, while it tends to correct the gibbosity by the exaggeration of the physiologic lordosis. The exposure of the uncovered back to the sunlight heals up the sources of suppuration. A complete cure with restoration of function is possible in nearly all the cases in which formerly we would have been well content with healing leaving a stiff joint. He has discarded plaster casts entirely and uses only apparatus for extension which facilitate the constant development of the muscles. One of the greatest advantages of heliotherapy, he adds, is that the cold abscesses heal without opening outward. Among his 158 cases of hip-joint disease, 125 were completely cured, with restoration of function in 102. In the 120 knee cases, 78 of the 106 cured cases have had function restored. In the 198 cases of Pott's disease, 171 are cured and 18 improved.

He regards his labor colony as an important factor in the result in some cases. This is an institution in which baskets and wicker chairs are made, the work done out of doors and the convalescents remunerated for their work. They are thus able to pay their way in part or in full and are not obliged to hurry away to support themselves before their cure is complete. He also has a farm colony where convalescents may aid in the raising of stock and bees, which has, in connection, a dairy and hot-houses for vegetables. These farm or greenhouse colonies could be founded anywhere, and they provide ideal conditions for those convalescing from tuberculosis while training them in scientific farming so that they can find employment later without returning to city life. He would like to see such institutions run by the state as subsidiary to tuberculosis heliotherapy institutions, preferably in the mountains. They would return to active life, in time, many tuberculous persons now destined to become crippled and to crowd our hospitals and homes for incurables.

Dr. Robert Bells Library

Kopp said that he prefers to operate in such cases unless the trouble is in the early stages or if it is too late to operate. These two groups are the only ones for which he thinks heliotherapy alone is adapted. In the intermediate cases the operation and healing in a few months should be balanced against the from one to three-year course of heliotherapy. It is possible that the latter may render unexpected services as an immediate supplement to operative measures, warding off recurrence. He joins in appealing to the authorities to organize state institutions for heliotherapy in charge of a skilled surgeon who does not expect the sun to do all the work.

Kocher reported the ultimate outcome twenty and twenty-five years after operative treatment of tuberculosis of the shoulder, elbow, hip joint and knee in 436 of his cases out of a total of 728. A number have died from progress of some preexisting focus elsewhere, but the results in the others are remarkably satisfactory. All the 28 surviving shoulder cases are entirely cured with free use of the shoulder, with one exception in which the shoulder functioning is defective. Of the 44 elbow cases, the arm can be used in all but 5; in 14 the joint is almost normally movable, in 16 it is stiff. He emphasizes, as the guide to treatment, the way in which Nature heals in casting off the tuberculous products. It is particularly impressive in the cases of open and multiple local tuberculosis which have healed under heliotherapy. With operative treatment the best results were always attained when the operation had been most radical.

63. **Tests of Kidney Functioning.**—Michaud refers only to those tests which reveal the part of the kidney involved in the nephritis. He tabulates his own findings in 110 cases and endorses Widal's classification of cases of nephritis into those with retention of salt in the blood and those with retention of nitrogenous substances in the blood. The retention of salt can be detected by regular weighing of the patient. A sudden increase of 1 kilogram in weight in nephritis corresponds to retention of 5 or 6 gm. of chlorids as a rule. Retention of nitrogen is revealed by regular examination of the proportion of nitrogen in the urine and of urea in the blood. Widal claims that the determination of the urea in the blood is more important clinically than determination of the proportion of albumin in the urine. The attempts to distinguish between glomerular and vascular nephritis have not given conclusive or instructive results, while classification of nephritis with high blood pressure and retention of chlorids or with retention of both salt and nitrogen, etc., points the way to treatment, as we thus learn exactly what the kidneys are incapable of doing.

66. **Hemoglobinuria Induced by Walking.**—There are several forms of paroxysmal hemoglobinuria, among which that caused by walking is the least known. Hemoglobinuria induced by cold is not very rare. The patients are generally syphilitics with vasomotor disturbances and attacks of chills, fever and prostration of moderate degree, with the hemoglobinuria and hemoglobinemia. Hemolytic substances are found in the serum that act only at low temperatures. The tendency may persist for years. Hemoglobinuria may also be caused by great muscular exertion, but only one case of this kind has been observed so far. The patient was not syphilitic. During the attack there were chills, fever, severe prostration, tendency to hemorrhage and degenerative paralyses of the muscles. There was hemoglobinemia but no hemolytic substances were detected in the serum.

The form discussed in this paper, hemoglobinuria brought on by marching, occurs in young persons with unstable vasomotor systems. The general condition is not affected during the attack; no fever, no complications. The prognosis is good. It disappears after a few months without special treatment. The attack is brought on by walking, more quickly by walking in a lordotic position. Hemoglobinemia and destruction of leukocytes are demonstrable, but no hemolysins could be found in the serum. Porges and Strisower think it is caused by an abnormal vasomotor reflex called forth by walking in a lordotic position. This acts on the spleen in such a way that an excessive number of erythrocytes are destroyed. The blood thus becomes flooded with hemoglobin and the limit of tolerance of the liver for hemoglobin is exceeded. Hemoglobinemia and hemoglobinuria result.

68. **Cell Inclusion Bodies.**—Döhle has described bodies found in the leukocytes that he considered pathognomonic of typhoid. They occurred in various forms, large and small round bodies, long bodies resembling bacteria, spirals and bodies resembling spirochetes. Döhle designated them "spirochetes," but as this would be apt to cause confusion, Rehder proposes the name "trypochetes." The views expressed with regard to these bodies by other writers since have shown entire lack of agreement. Some authors hold that they are found only in scarlet fever and others that they are so common as to be almost normal, or at least that they are present in persons after recovery from a great variety of diseases. In order to settle the question if possible, Rehder made examinations of over 1,200 blood smears from over 200 patients. He thinks the confusion is due to the fact that some observers counted everything as inclusion bodies, even the smallest specks seen in the leukocytes, while others counted only the typical trypochetes. He classes the round and long formations as atypical inclusions, and the spirals and trypochetes as typical inclusions. He found typical inclusions in twenty-four out of thirty-nine cases of scarlet fever. They were more abundant in the severe cases than in the mild ones, and during the first days of the disease than later. In a series of other eruptive diseases that might be confused with scarlet fever, he found them only very rarely, while atypical inclusions were found in a great number of infectious diseases; they were relatively most frequent in tuberculosis. This explains the conflicting findings of other writers. Rehder considers the inclusions of diagnostic value in scarlet fever. He does not attempt to explain their real nature, though he thinks they are related to the protoplasm of the leukocyte. He does not agree with Döhle who believes that they are protozoa and the cause of scarlet fever.

74. **Suggestion and Drugs.**—Weintraud refers in particular to a proprietary formaldehyd preparation which he has been thoroughly testing. He found it harmless but never witnessed the slightest objective benefit from its use. In connection with this he discusses the psychology of patients, their dislike to have any disturbances explained as "merely a nervous trouble." It is impossible to convince them that all or part of their disturbances is merely the result of some emotional stress in the past, possibly long forgotten. The physician has to distinguish between what he calls legitimate and illegitimate pains, that is, those that can or cannot be explained by some adequate irritation at the periphery in

some connection with the spot where the pain is experienced. It wounds the patient's vanity to have the pains explained as of the illegitimate type, and it is this class which turn to quacks.

80. **Chlorinated Lime in Prophylaxis of Tetanus.**—Riehl has been advocating for several years the use of bleaching powder for treatment of snake-bite. Calmette and Paltauf found chlorin effectual in treatment of animals injected with cobra venom in doses otherwise fatal, and Riehl got up a little case for persons exposed to snake-bite. The case contains a syringe, two needles, a measuring glass and a few 0.25 gm. tablets of chlorinated lime (bleaching powder). The measuring glass is filled with water up to the 15 gm. mark and one tablet is dissolved in it. The chlorin water thus produced is equivalent to 850 c.c. of chlorin gas in 1,000 gm. water. In case of snake-bite a tourniquet is applied to the limb above the bite and the chlorin solution is injected around the spot and into the subcutaneous tissue and muscle. The procedure has proved its usefulness in numerous instances. As chlorin destroys cobra toxin, Riehl is convinced that it will act in the same way on tetanus toxin, in addition to its familiar powerful action as a disinfectant and deodorizer. It seems thus destined to find wide use in warding off and treating tetanus. A mixture of one part chlorinated lime to nine parts bolus alba (kaolin) has proved the most convenient method of its use. It is sifted freely into wounds or blown in, powdering the whole of the wounded area thick with it. There is no pain from its application, while the wound cleans up and heals remarkably under it. The earlier it is applied, the better the effect, and Riehl urges its extensive use for all shell wounds and other contaminated wounds.

83. **Autohematherapy.**—Spiethoff's further experience has confirmed the excellent results from reinjection of the patient's own blood or serum in various skin affections, especially in eczema and itching dermatoses. (A previous communication on the subject was summarized in The Journal, July 26, 1913, p. 315.) He has never had any mishaps with his intravenous technic but he has discarded the second cannula which he advocated in his earlier report. He uses a cannula as wide as can fit into the vein, and in some cases repeats the injection daily or even twice daily, injecting up to 100 or 200 c.c. of blood each time, keeping it up sometimes for weeks. As there are no disturbances afterward, he says, the injections can be done on out-patients. He claims for this autoserotherapy or autohematherapy all that can be obtained from simple serotherapy under any conditions, while the advantages of freedom from danger of anaphylaxis and of contracting disease from another person as well as the saving of time, are important points in its favor. He explains the result as due to a modification of the reaction of the skin to irritation from any source. No case-histories are given here.

90 *Calcium Phosphate in Treatment of Rachitis. L. Frank and E. Schloss.
91 *Treatment of Spasmophilia with Phosphorized Cod Liver Oil and Calcium Phosphate. E. Schloss.

90. **Cod Liver Oil and Calcium Phosphate in Treatment of Rachitis.**—This is Schloss and Frank's seventh communication on the treatment of rickets since early in 1913, publishing the favorable effect in rickets of treatment with cod liver oil and calcium phosphate. They have already reported fifty-four metabolism experiments showing that this method of treatment is justified in general practice. But as this treatment seems to be in contradiction to the generally accepted theories with regard to rickets, it was deemed advisable to take up still further experiments to exclude any doubt. These experiments were designed to show the permanency of the good effects obtained. Thus seventy-eight further experiments are described, with tables and weight curves. The medication was given for at least a week before the metabolism experiments were made, to be sure that the metabolism had become adapted to the new conditions. Further investigations were made at regular intervals to show the constancy of the effect. The experiments extended over two or three months for each child and the findings in five-day periods are given for seventy-eight series of investigations. Children were selected in whom the rickets had begun early and made marked progress, except one in whom rickets had just manifested itself, and the treatment was given for prophylactic purposes. The cod liver oil and tricalcium phosphate were given in the form of an emulsion. (See following abstract for formula.) The experiments show that the treatment in the earlier as well as in the later stages of rickets brings about marked improvement in the calcium and phosphorus balance. The effect does not disappear on long continued use of the medication but rather seems to increase. After cessation of the treatment, the balance of the bone-forming minerals continues better than in the preliminary period, which is a sign of the permanency of the effect of this treatment. It is also manifested clinically by disappearance of the softness of the bones.

91. **Treatment of Spasmophilia with Cod Liver Oil and Calcium Phosphate.**—Schloss used this treatment, advocated above, in spasmophilia also. His material is very small—only 4 cases—but in all these cases the symptoms, the spasm of the larynx, Chvostek's sign and increased electrical excitability, disappeared permanently after the administration of 10 gm. cod liver oil and 1 gm. tricalcium phosphate. He thinks that calcium phosphate is to be preferred to calcium chlorid, which has been recommended by some, because the chlorid, which must be given in large doses, has certain bad effects on the child, while phosphorus has an exceptionally good effect in nervous complaints. The prescription calls for 10 gm. calcii phosphoric. tribasic. puriss. in 100 gm. ol. jecor. asell. The dose is 5 gm. twice a day, shaking well before using.

92. **Clinical Signs of Incipient Weakness of the Heart.**—Moritz comments on the fact that the symptoms noticed with incipient weakness of the heart can be caused by vasomotor influences, and hence it is not easy to ascertain the exact share of the heart in enlargement of the liver, in edema and in albuminuria, for example. There is scarcely a single symptom which testifies unmistakably to weakness of the heart; it is only by estimating the disturbances as a whole that it is possible to exclude other causes, especially the "merely nervous" disturbances. The pulse is one function of the heart, but it is not a measure of its force until the heart has reached the limit of its powers. Even with insufficient heart action, the arterial blood pressure may be normal or above. An abnormally high blood pressure is a sign merely that the heart is being called on for an extra amount of work, and hence measures are needed to reduce its task to prevent its getting worn out. The venous blood pressure is more instructive; abnormally high pressure in the ulnar vein indicates stasis at this point. The test is applied with the patient reclining; one leg is held up in the air and the effort of doing this induces an abnormally high pressure in the ulnar vein if the pumping force of the heart is below par.

Gradual acceleration of the pulse at rest is an important sign of encroaching weakness of the heart, as also acceleration persisting after physical exercise. He tests this by taking the pulse, reclining, and then again, reclining, after a series of ten exercises in bending the knees. In less than two minutes afterward the accelerated pulse has dropped back to normal when the heart is sound, but it keeps fast if the heart has begun to weaken. The pulse is still fast if examined while the patient is asleep that night.

Moritz has found that the average heart beat during sleep at night is 57, averaging about 20 per cent. less than during bed rest while awake. Even a sound heart shows the effect at night of considerable exercise, such as bicycling, during the day; the pulse is higher than under other conditions. When even a sound heart shows such an effect, the effect on a weakened heart must be correspondingly greater. When the acceleration of the pulse is of purely nervous origin it usually subsides during sleep, but acceleration from cardiac insufficiency keeps up proportionally, even during sleep at night.

He has encountered many instances of overexertion of the heart among the troops at the front. In three cases the heart sounds were pure and the organ was not enlarged but the pulse in repose was 96, 108 or 132, the only objective findings to explain the oppression in the chest, the dyspnea or the extreme exhaustion observed. Abnormal readiness to fatigue or exhaustion may be the first sign of the heart's not being quite up to par. Another sign is a tendency to yawn during exertion. The connection of various disturbances with preceding exercise speaks against a nervous origin for them. A feeling of suffocation may sometimes occur from psychic influences alone; exercise relieves it while exercise has a tendency to aggravate dyspnea from heart weakness, anemia or respiratory trouble.

Cardiac asthma coming on at night with coughing and copious thin and foamy sputum is a mild form of edema of the lungs. A common form of cardiac dyspnea is that which comes on as the individual drops to sleep. This may occur repeatedly, especially when the arterial blood pressure is high. Contracted kidney is frequently encountered under these circumstances. The discovery of hypertonicity with these disturbances points to a periodical nocturnal weakness of the heart. Such patients are mostly elderly. The heart, apparently normal at other times, reveals its latent weakness as sleep puts an end to sense stimuli which aid to maintain tonicity during the waking hours. Recognition of this early sign of insufficiency permits proper treatment—camphor or morphin for temporary aid, followed by a mild course of digitalis, supplemented possibly by venesection. Another early sign, and perhaps long the only one, is a gallop rhythm. This also calls for digitalis, as it indicates, he says, stagnation of blood in the left auricle as the ventricle contractions grow weaker. The presystolic gallop is the more common, and the blood pressure with it is abnormally high.

94. **Injection of Alcohol Into the Gasserian Ganglion.**—Hirschel reports that there has been no recurrence of the extremely severe trigeminal neuralgia in the seven cases in which he blocked the gasserian ganglion by injection of alcohol. In two there was only slight improvement at first but gradually the cure became complete.

98. **Wire Extension from the Heel.**—Burger has applied in fourteen cases Klapp's method of suspending a weight from a wire passed through the heel. The ends of the wire are brought through a board below, the holes far enough apart to hold the ends of the wire parallel as they pass down the sides of the heel. He regards this as a simple and effectual method for extension. Some of the patients did not complain of any painfulness from it, and the others did not mind the slight pain at first.

99. **Tetanus.**—Schneider states that none recovered of the tetanus patients treated with subcutaneous injection of antitetanus serum while three of the nine given intravenous injections were saved out of a total of twenty-two cases. The wounded are apt to ascribe to their wound the first faint symptoms of tetanus, so the physician must make special inquiry for slight "rheumatic" pains and stiffness in the wounded limb, fatigue in chewing, pains around the mouth and brief cramps in the chest muscles, like a "stitch in the side."

102. **Arrest of Hemorrhages in Sepsis.**—In Kronheimer's two cases, a tendency to recurring severe parenchymatous hemorrhages, accompanying extensive septic wounds, was arrested by subcutaneous injection of 2.5 c.c. of fresh human serum repeated with twice the dose three days later in one case. In the other, 5 c.c. was injected each time. The hemorrhages did not recur afterward, although the first patient's history suggested a tendency to hemophilia.

106 Estimation of Past Intervals of Time Almost Always Shortens Them. (Zur Schätzung der verflossenen Zeit und ihre Rolle bei der Aufnahme von Krankengeschichten.) J. Kollarits.

103. **Treatment of Exophthalmic Goiter.**—Von Haberer's success in treating exophthalmic goiter by resection of the thymus was reported in these columns last year, July 25, 1914, p. 361, and October 3, p. 1237. The Basedow symptoms rapidly subsided and the improvement was durable in his twenty-one cases. These favorable permanent effects contrasted with those in other cases in which the thyroid alone had been resected, emphasized the important part which the thymus must have played in the Basedow syndrome. He here reports three additional cases in which the indications were apparently the same; a severe form of exophthalmic goiter was accompanied by symptoms showing disturbance in both the vagus and sympathetic nervous systems, in short, the syndrome calling for resection of the thymus. In the first case the young woman for twelve hours seemed much relieved by the resection of both thyroid and thymus as in his preceding successful series, but the next day she was restless, the pulse 160. The restlessness increased and the pulse ran up to 200, with fever and much cyanosis and the woman died the third day. There was thus the same fatal aggravation of the Basedow symptoms as sometimes follows resection of the thyroid alone, except that there had been a twelve-hour period of relief before the symptoms returned. The case seemed to upset the conception that the thymus

is responsible for the major part of the symptoms, as he had excised a large piece of the thymus. Necropsy, however, steadied this conception on even a more solid base, as it showed that although a piece of the thymus nearly as large as an ordinary thymus had been resected, yet this was only a small fraction of the thymus in this case. What was left weighed 70 gm. The article is to be concluded in No. 2.

110 *Aleukemic Myelosis. II. (Le mielosi aleucemiche eritroblastiche dal punto di vista clinico.) G. Ghedini.

109. **Rapid Loss of Pharmacologic Power of Atropin.**—Simon has been experimenting on rabbits to learn how soon an aqueous solution of atropin loses its power to paralyze the vagus. He tabulates the findings in thirteen experiments, all testifying that in three days from the making of the aqueous solution not only the minimal dose that paralyzes the vagus under other conditions, but much larger doses, fail to paralyze the vagus. The minimal dose per kilogram of weight is not much larger for the rabbit than for man. He advises druggists to keep on hand vials with a capacity of 10 c.c. but containing 0.01 gm. atropin sulphate. In another vial 10 c.c. of water is kept, and both vials are sterilized. Then by pouring the water on the atropin, the sterile 1 per thousand solution is ready in a minute.

110. **Aleukemic Myelosis.**—This is the second instalment of Ghedini's study of what he calls erythroblast aleukemic myelosis. The spleen is enlarged in every case, but there may be abnormally large numbers of red blood cells, with or without subleukemia, or there may be abnormally small numbers of blood corpuscles with or without chronic jaundice, sometimes associated with cirrhosis of the liver. These combinations form five different types of aleukemic myelosis. He discusses each in turn, theorizing to explain the phenomena observed. They are all links of the same chain, he thinks, all traceable to a single fundamental cause acting on a predisposition, congenital or acquired, on the part of the myeloerythroblast apparatus, analogous to the territorial predisposition we style the lymphatic diathesis.

111. **Autonomous Innervation of the Striated Muscles.**—De Boer's article is accompanied by forty-one illustrations or diagrams showing his findings on frogs and cats.

112. **Fat Embolism.**—Nicolai discusses the literature on this subject in connection with the case of a middle-aged man who met with an accident in which one leg and several ribs were fractured. Respiration and pulse were accelerated thereafter and coma developed the second day with death the third. Necropsy revealed fat embolism as the cause of death.

114. **Treatment of Varicocele.**—Van Dijk tabulates the details of forty-eight cases of varicocele in which he resected the pampiniform plexus in treatment and reexamined the patients from one to twelve years afterward. The disturbances from the varicocele are due almost entirely to the pressure on the pampiniform plexus, and Bennet's method of resecting the entire plexus, from the external inguinal ring to the epididymis, is, he insists, the logical and effectual treatment. In case of hydrocele, the tunica proper of the testicle can be incised and turned back by Winckelmann's technic.

118. **Influence of Ischemia on Local Tuberculous Processes.**—Elkind performed eighty experiments on rabbits for the purpose of studying the effect of ligation of the renal artery on tuberculous infection of the kidney involved. A virulent culture of tubercle bacilli was injected into the parenchyma and pelvis of the left kidney. Simultaneously the left ureter was ligated in some rabbits. In others the tubercle bacilli were injected into the vein of the ear and, some time after the infection had set in, the renal artery was ligated. Those rabbits that survived the operation were killed about four months after the ligation, when the contracted kidney could no longer be palpated. The rabbits that survived the ligation of the renal artery rapidly improved and gained in weight, the temperature becoming normal. The kidneys were found studded with tubercles but the nodules had gradually shrunk, showing a proliferation of connective tissue and infiltration with lime. The tuberculous foci were found walled in with fibrous capsules of varying thickness. Thus regressive changes in the tuberculous kidney were plainly evident as the result of the artificially induced ischemia, just as occurs in the lungs after ligation of the branches of the pulmonary artery.

119. **Prophylactic Treatment of the Peritoneum Before Operations.**—Lissovskaia and Djanelidze injected camphorated oil into the abdominal cavity in cases of acute purulent and adhesive peritonitis, but without any good results. In one patient with adhesive peritonitis that had followed an appendicitis operation, 15 gm. of liquid petrolatum were injected into the abdominal cavity after the adhesions were separated. The patient felt well for about five months when the old complaints reappeared. Blue-light treatment gave some relief. Experiments with injection of liquid petrolatum into the peritoneal cavity of rabbits after the serous covering of the small intestines had been detached, proved that liquid petrolatum may remain in the body for a long time without affecting the general condition of the animals, but it causes some peritoneal irritation. Therefore liquid petrolatum can not be relied on to prevent postoperative peritoneal adhesions. The treatment of the latter must be prophylactic—absolute asepsis, careful handling of the peritoneal covering of the intestines, prevention and careful arrest of hemorrhage, etc.

120. **Functional Deficiency in Stomach and Pancreas Secretion.**—Some of the conclusions Orloff came to from his studies of twenty-eight patients with different diseases are that functional achylia of the stomach and pancreas may occur together. Also that in gastric achylia there eventually occurs a vicarious increased secretion of trypsin. In pancreatic achylia the secretion of the diastatic ferment probably suffers also. Pancreas extract in treatment for pancreatic achylia gave good results in his experience.

121. **Excrescences on the Heel Bone.**—Kanevshaia points out the frequency of exostoses on the os calcis—calcaneum

spurs—as the cause of pain in the heel. This cause should be looked for in patients suffering from varicose veins in the legs, as such patients frequently complain of circumscribed pain in the feet. In cadavers these excrescences are found in about 9 per cent. They are bilateral and occur in males more frequently than in females, but do not seem to develop before the age of 15. Those exostoses that occur in arteriosclerosis and gout are not true excrescences but are merely deposits of salts in the soft tissues. The pain is due to the crushing or fracture of the exostosis, to bursitis or derangement of the arch or to pressure of the bone growth on the soft tissues. The pain does not radiate. The most rational treatment is surgical; the bursa should be removed also. To avoid possible relapses, arch supporters should be worn even if the present flat-foot does not cause any trouble.

122. **Communication Between Esophagus and Air Passages.**—In Rashb's three cases the causes of the esophagotracheal fistula were in two cases carcinoma of the esophagus and in one trauma of the esophagus caused by a swallowed bone. The most prominent clinical symptom was severe coughing after swallowing food, especially fluids. Part of the swallowed food was expelled with the sputum. In case this symptom is not pronounced, endoscopy may help the diagnosis. The prognosis is absolutely bad, as the patients inevitably succumb to aspiration pneumonia.

124 *Surgical Treatment of "Medical" Nephritis. (Erfaringer om kirurgisk Behandling af de kroniske aseptiske "medicinske" Nefriter.) T. Rovsing. Commenced in No. 1.

123. **Paraffin Mixture with Low Melting Point.**—For embedding tissues, Jensen uses a mixture of two parts paraffin with a melting point at 56 C.; two parts paraffin with a melting point at 40 C., and one part spermaceti. This mixture is as transparent as pure paraffin and the melting point is about 41 C. He treats the specimen first with alcohol and then with benzin before transferring it to the melted paraffin mixture.

124. **Surgical Treatment of Chronic Aseptic Nephritis.**—In forty-six cases of chronic, aseptic "medical" nephritis Rovsing has applied nephrolysis. This is practically the same as Edebohls' decapsulation. Rovsing had published this nephrolysis method in 1895, some time before Edebohls' publications. He is much more cautious in accepting indications for it than Edebohls, and he also explains its mode of action somewhat differently. Rovsing's cases have shown that medical nephritis may be restricted to one kidney alone, and there are grounds for supposing that this is not uncommon not only with interstitial but with parenchymatous and glomerular nephritis. He urges internists to draw the urine from each kidney and examine it separately. Especially in case of hemorrhagic nephritis, this may be of vital importance as simple nephrolysis may cure parenchymatous and glomerular nephritis of one or both kidneys.

He slits the membrane proper, breaks up adhesions, and resects as much as possible of the adipose capsule if it shows fibrous degeneration. Incision of the kidney itself he denounces as dangerous and unnecessary. He comments on the comparative indifference of the internists to the etiology, diagnosis and classification of the different forms of chronic nephritis. Internists to-day, he declares, in the field of chronic nephritis are no further advanced than those of the last generation, and they have given little help to the efforts of the surgeons to cure aseptic nephritis. Among his forty-six patients, twenty were women. He excised a scrap of the kidney for examination in nearly every case.

In the thirteen cases of interstitial nephritis, perinephritis with paroxysmal pains and hematuria but no albuminuria, all the patients were clinically cured by the nephrolysis. In the majority the interval since has been over seven years. In sixteen other cases the syndrome was the same plus albuminuria, and all these patients have been cured, with two exceptions. In one patient the other kidney now calls for nephrolysis; another patient died. This latter was the only case in which the kidney proper was incised. It illustrates the danger of nephrotomy, while all the other cases in these two groups confirm the needlessness of any measures beyond the nephrolysis. The outcome of the nephrolysis confirmed the assumption that the nephritis affected only one kidney in most of the cases. It demonstrated further that simple nephrolysis not only cured the pains and hematuria but also the albuminuria. The albumin was materially reduced or disappeared entirely for a longer or a shorter time, and in the majority has not reappeared during the seven to nine years since.

Among his six cases of diffuse parenchymatous nephritis some were hemorrhagic, and in one he expected to remove the kidney, as the patient had long suffered from pains in the right kidney region. A gynecologist had diagnosed pyelonephritis, had prescribed hexamethylenamin and sent her to the hospital for nephrectomy. She improved at first but severe bladder tenesmus returned, and fibrinous clumps were passed in the urine, while the albuminuria increased. No bacteria were found in the urine. When the kidney was exposed, Rovsing contented himself with nephrolysis instead of removing the organ. The albuminuria and the pains subsided at once, but two weeks later there was a new attack. It coincided with resumption of the hexamethylenamin and when this was stopped, all disturbances ceased at once. He is convinced that the hexamethylenamin (urotropin) was responsible for all the syndrome that was not the result of the perinephritic adhesions. The drug induced albuminuria, a toxic cystitis, and desquamation of epithelium, thus setting up a vicious circle.

No benefit was apparent from the nephrolysis in four other cases of diffuse parenchymatous nephritis; but in the sixth case nephrolysis on both sides seems to have cured the patient completely after medical treatment for months had failed to relieve the bilateral nephritis with much albuminuria, and occasional hematuria. In his three cases of glomerular nephritis, it was bilateral in one case and only transient benefit was realized from the nephrolysis. In the two others only one kidney was involved and one patient has been entirely well during the seven years since the successful nephrolysis. The other patient had hemorrhages later, compelling nephrectomy, and has been in good health since this operation.

The nephrolysis did not benefit in the one case of orthostatic albuminuria in which it was applied. He now orders, in such cases, extra nourishing food, and tells the patient to lie down for one or two hours a day and never to stand long at a time. He asserts that a supporting bandage is an important aid in the cure of the wandering kidney which is the main factor in orthostatic albuminuria. As the patient stands up, the kidney becomes dislocated and albuminuria is the natural result. In one case both kidneys were loosely movable and the albuminuria and other disturbances compelled nephropexy on both sides, after which there was no further trouble.

CANCER OF THE BREAST*

W. L. RODMAN, M.D.
PHILADELPHIA

Cancer of the mammary gland is second in frequency only to carcinoma of the stomach. When a clinical diagnosis of it can be made with reasonable certainty it is oftentimes too late for a radical cure to be effected, because it has ceased to be a strictly local condition, as are all such lesions in their incipiency, but instead, has, through metastases, become a general and therefore necessarily lethal disease. A late diagnosis cannot be atoned for by a more extensive operation, as operative measures have already been carried to the farthest possible limit. Therefore our best endeavors should be enlisted in the direction of earlier diagnoses, or, better still, we should attack all lesions that are potentially malignant and remove them at a time when their hosts can safely, certainly, and quickly be cured. The presence of so many laymen to-night would seem to make it necessary to emphasize what has long been known to surgeons and pathologists, that cancer is primarily of local origin. Further, there are many in the profession, a few in high authority, who still cling to a teaching which is as archaic as it is unfortunate. Moore of London demonstrated in 1867 that cancer *begins always* as a strictly local disease. The evidence is clinical, microscopic, experimental and surgical, and no jury reviewing it can fail to find a prompt verdict. The clinical evidence alone is suggestive, indeed, well-nigh conclusive. Early in the disease a patient seems in every way to be in perfect health. They are well nourished, they have no pain, they eat, sleep, look and feel perfectly well. Could this be so if the disease were constitutional?

The microscopic evidence is conclusive as to the local nature of the affection: if one cuts through the center of a growth, and places a section under the microscope, there will be seen countless epithelial cells pathognomonic of cancer. At the periphery of the tumor such cells become fewer in number, and, just beyond its edge there are few, or none at all. Can this mean but one thing—a local neoplasm?

If a mouse is injected with cancer cells there will, in time, appear a small tumor at the identical spot where the injection or needle puncture was made. It grows slowly but steadily, and there is no tumor or swelling at any other place. The mouse seems as well as any others with which it may be placed. It eats, plays, sleeps, and behaves in every way as other mice do. Later on secondary swellings, or tumors, appear over other parts of its body, and simultaneously with them the animal loses its appetite, evidently has pain, becomes emaciated, and finally dies. Plainly the disease is now constitutional, the blood and many solid tissues being involved. But as weighty as the clinical, microscopic and experimental evidence is, the surgical is by far more convincing. If the small growth be excised, along with a fair amount of the tissue immediately adjacent thereto, so as to get beyond any outlying cancer cells, or as a layman would say, "the roots," the wound made in so doing quickly heals and that is the end of the trouble. It never returns *in loco* or elsewhere. All depends on the thoroughness of removal.

It would be interesting, if time allowed, to prove this incontestably by reviewing operative results from the time when operators were pessimistic and faint hearted, practicing only partial or incomplete removal, with the far better results secured at the present time when a judicious optimism prevails with all up-to-date surgeons, who, accordingly, institute radical procedures and usually eradicate the disease. We could show how operative results have improved not only with each decennial or quinquennial period, but, in fact, have improved year by year since Moore's epoch-making discovery. The forceful teachings of Moore and Banks of England, Billroth and Volkmann of Germany, and Gross, Halsted, Warren, Meyer, and others in America have long since been accepted without question and should be thundered from the very housetops. Every patient with early cancer of the breast, every physician consulted on account of it, should know that prompt and radical surgical treatment offers almost certain relief. If it does not follow, somebody has blundered. Usually it will be the unfortunate host, who has suffered so little inconvenience thereby as to think it trivial and refuse to seek advice. It may be the physician who prefers "to wait and see if it is malignant" before advising its removal; or, it may be the surgeon who performs an incomplete operation. Nevertheless, there *was* a time when a definite and permanent cure would have been not only possible but next to certain. Should we not, therefore, pull together and not apart?

We have said that early diagnosis and prompt surgical intervention are both necessary. Can an early clinical diagnosis always be made? No, but us
it can be done, and in doubtful instances the

* Address before the Southern Medical Association in Richmond, Va., Nov. 11, 1914.

report after making frozen sections. This can be done in five minutes, and the action of the surgeon depends entirely on the report of the pathologist, which should be both accurate and dependable.

Every one familiar with pathologic conditions in the mammary gland knows that a vast majority of them are either malignant or potentially so. All should therefore be considered malignant until found to be benign. In patients who have reached the age of 40 or upward, the immense majority are malignant *ab initio*. But we have been too dogmatic in the past in declaring that cancer is an affection of middle or advanced life. Twenty per cent. of carcinomas of the breast occur in women under 40, and I recently encountered it in a girl of 17. Moreover, when it does occur in young women, it is relatively more fatal than in older ones. It is therefore even more necessary to act promptly.

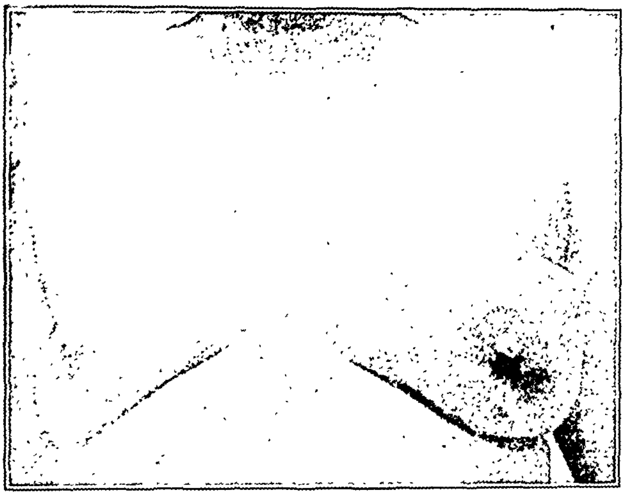

Fig. 1.—Growth clinically diagnosed as a sarcoma in a woman 47 years old. Pathologically diagnosed as either a myxoma which has undergone sarcomatous change, or benign growth.

Why is it more fatal in the young? Because their lymphatic vessels are both more numerous and patent, and hence a strictly local process soon becomes a general or disseminated one. In short, the lymphatic glands become involved at an earlier stage in the young, and when such is the case, the chances of a radical cure are about one-fourth as great as when they are not involved. Twenty-five per cent. of the patients with axillary involvement are cured by operation; 80 per cent., or more, when there is no such involvement. Could a better reason be given for prompt action, as no one can foretell when the axillary glands may become involved? They are practically always infected within a twelvemonth after the local appearance of the growth in the breast, and may be so much earlier. The unger the patient, the sooner the involvement.

ficult as it is clinically to distinguish with cer- d between benign and malignant solid growths, difficulty is greater when the two varieties of cysts re considered, and greatest when abnormal involution d carcinoma are to be differentiated. The micro- pe, and it only, can be relied on. The only safe is to obtain the consent of the patient to a com- operation, should it be necessary, the surgeon governed absolutely by the report of the patholo- ased on frozen sections. Patients have a right fit by their own pathology, and it is the duty of In eon to have at hand a competent pathologist alb to render him prompt and accurate aid. In my judgment it is now impossible, perhaps always will be so, to make a diagnosis reasonably certain in any other way. For instance, in a careful analysis of sixty-five cases of abnormal involution or chronic cystic mastitis coming to operation at my hands, fourteen, or 21.5 per cent., had undergone undoubted carcinomatous degeneration when operated on; in some the malignant changes were advanced, in others just beginning. Speese found 25 per cent. of the patients operated on at the clinics of the University of Pennsylvania showing carcinoma, and a recent report from one of the German clinics (Bertel) showed that 25 per cent. of the abnormal involution cases there operated on had already undergone malignant degeneration. I feel, therefore, that the percentages given by Warren (13) and Greenough and Hartwell (10) are too low. But even if they are not, and the chances are only half as great, it would be unfair to the patient and unjust to the reputation of the surgeon to withhold any information that may be helpful. Partial operations in chronic cystic mastitis are rarely justified in those who have reached the age of 40, and should not be practiced at all, even in younger women, unless the microscopic report seems to make it safe. But, even though malignant change has not already begun, who can say that it will not take place at some future time, with a con-

wer t

irst suggested been generally adopted instead of calling the disease by the name of one who so accurately lescribed it.

Cancer and abnormal involution are the two most ommon diseases of the breast, as will be seen by an analysis of two hundred of my consecutive private cases (Table 1).

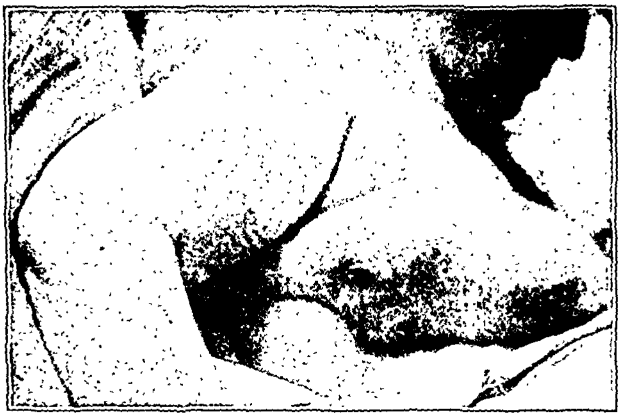

Fig. 3.—Ulcerating tumor.

TABLE 1.—DISEASES OF THE BREAST IN TWO HUNDRED CASES

	Number	Per Cent.
Carcinoma	83	41.5
Abnormal involution	67	33.5
Benign tumors	30	15
Papillary cyst adenoma	6	3
Tuberculosis	6	3
Sarcoma	5	2.5
Galactocele	3	1.5
Total	200	100

If we add the six cases of papillary cyst adenoma to the sixty-seven of abnormal involution we have seventy-three so-called benign cases and eighty-eight malignant ones in a series of two hundred. Hence they are about equally common. The potential malignancy of papillary cyst adenoma is much greater than that of abnormal involution, as the tumors in five of my six patients showed marked cancerous degeneration. In fact, I no longer consider this disease as benign. That it begins as such is true, perhaps, but it so quickly tends to assume a malignant phase that it is safe only to consider it as malignant and to treat it in the most radical manner. The same is equally true of Paget's disease. The eczema of the skin is the secondary manifestation of duct cancer and is due to the irritating discharge from within the ducts. The proof of this is found in the fact that the deeper we go, the more marked evidence we have of malignancy, whereas, if the superficial condition were the original one the reverse would be true. Thin, Raymond Johnson, Williams and others were fairly prompt to controvert the views of Sir James, but the latter's more commanding position and his forceful presentation of his case caused his view to be accepted as an ex-cathedra utterance.

How is cancer of the breast to be treated? Understanding as we now do, that it is strictly a local affection primarily, the answer should always, and without exception, be as direct and positive as language can make it. Free and early excision by the knife is the only thing to be considered, because one can never tell the extent of the disease until the lesion and surrounding tissues have been examined by sight, touch and the microscope so that the surgeon may know that his work has been rightly and thoroughly done. Hence the utter futility of caustics, radium, Roentgen rays, etc. There are conditions less pitiless and destructive in their nature in which second- and third-best remedies may be used if, through a fancied dread of a surgical operation, the patient insists on them. But cancer is not one of them, and the medical man is recreant to his trust if he does not protest against a course which means almost certain disaster. The danger of an operation at this time is, at the most, one-half of one per cent., and if performed early nearly all will result in a permanent cure. Even when cancer has been present for a year the chances of success are about equal. After more than a year's duration one-third, one-fourth or less will be cured, according to the extent of the growth, its location, the age of the patient and other circumstances. Can more reasonably be expected of any treatment for a disease that will almost certainly prove lethal in thirty-six months without treatment? Cancer is curable and its existence in the breast, or other external organs, should, from its very nature, be evident quite soon; therefore the responsibility for so many deaths (18,000 annually from cancer of the breast in the United States[1]) rests with the hesitating hosts or the equally dilatory physician who is first consulted. It is no fault of the cancer, for there is visible evidence of its presence long before it has ceased to be a local and removable enemy. But both patient and physician may answer, "Yes, I knew there was a tumor present, but did not suspect that it was serious." Lumps or tumors of the breast are always serious and presumably malignant until the contrary is established, for I have shown that of 200 of my private patients taken consecutively, 161 were either malignant or potentially so. Add to them the six cases of tuberculosis, in which it is almost as necessary to have a radical operation, and the number is increased to 167. With such melancholy facts staring one in the face, why will women and their family physicians continue to act as little children who play with fire? It passeth all understanding, yet they do. Those who act promptly are as the wise, those who are tardy as the foolish virgins. Does not the drowning person catch at anything, even straws, before going down? But the victims of early cancer have a life boat into which

Fig. 4.—Sarcoma.

---

[1] There were 75,000 deaths from cancer, and it is customary to estimate that 25 per cent. approximately were due to mammary carcinomas.

report after making frozen sections. This can be done in five minutes, and the action of the surgeon depends entirely on the report of the pathologist, which should be both accurate and dependable.

Every one familiar with pathologic conditions in the mammary gland knows that a vast majority of them are either malignant or potentially so. All should therefore be considered malignant until found to be enign. In patients who have reached the age of 40 r upward, the immense majority are malignant *ab nitio*. But we have been too dogmatic in the past in declaring that cancer is an affection of middle or advanced life. Twenty per cent. of carcinomas of the breast occur in women under 40, and I recently encountered it in a girl of 17. Moreover, when it does occur in young women, it is relatively more fatal than in older ones. It is therefore even more necessary to act promptly.

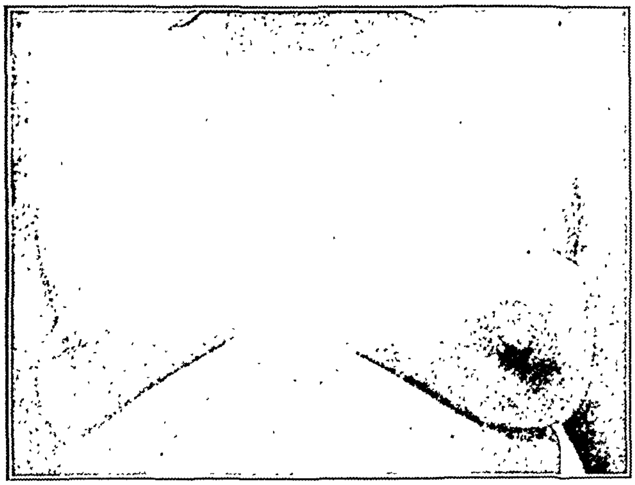

Fig. 1.—Growth clinically diagnosed as a sarcoma in a woman 47 years old. Pathologically diagnosed as either a myxoma which has undergone sarcomatous change, or benign growth.

Why is it more fatal in the young? Because their lymphatic vessels are both more numerous and patent, and hence a strictly local process soon becomes a general or disseminated one. In short, the lymphatic glands become involved at an earlier stage in the young, and when such is the case, the chances of a radical cure are about one-fourth as great as when they are not involved. Twenty-five per cent. of the patients with axillary involvement are cured by operation; 80 per cent., or more, when there is no such involvement. Could a better reason be given for prompt action, as no one can foretell when the axillary glands may become involved? They are practically always infected within a twelvemonth after the local appearance of the growth in the breast, and may be so much earlier. The unger the patient, the sooner the involvement.

ficult as it is clinically to distinguish with cer- between benign and malignant solid growths, difficulty is greater when the two varieties of cysts re considered, and greatest when abnormal involution d carcinoma are to be differentiated. The micro- pe, and it only, can be relied on. The only safe is to obtain the consent of the patient to a com- operation, should it be necessary, the surgeon governed absolutely by the report of the patholo- ased on frozen sections. Patients have a right t by their own pathology, and it is the duty of eon to have at hand a competent pathologist to render him prompt and accurate aid. In my judgment it is now impossible, perhaps always will be so, to make a diagnosis reasonably certain in any other way. For instance, in a careful analysis of sixty-five cases of abnormal involution or chronic cystic mastitis coming to operation at my hands, fourteen, or 21.5 per cent., had undergone undoubted carcinomatous degeneration when operated on; in some the malignant changes were advanced, in others just beginning. Speese found 25 per cent. of the patients operated on at the clinics of the University of Pennsylvania showing carcinoma, and a recent report from one of the German clinics (Bertel) showed that 25 per cent. of the abnormal involution cases there operated on had already undergone malignant degeneration. I feel, therefore, that the percentages given by Warren (13) and Greenough and Hartwell (10) are too low. But even if they are not, and the chances are only half as great, it would be unfair to the patient and unjust to the reputation of the surgeon to withhold any information that may be helpful. Partial operations in chronic cystic mastitis are rarely justified in those who have reached the age of 40, and should not be practiced at all, even in younger women, unless the microscopic report seems to make it safe. But, even though malignant change has not already begun, who can say that it will not take place at some future time, with a condition present which is always admittedly potentially malignant? Reclus, one of the very first to study this disease, gave it the name of intra-acinous cystic epithelioma, showing that he recognized clearly enough its potentialities. It is therefore to be regretted that his first observations were for a long time forgotten. It were much better had the pathologic name which he

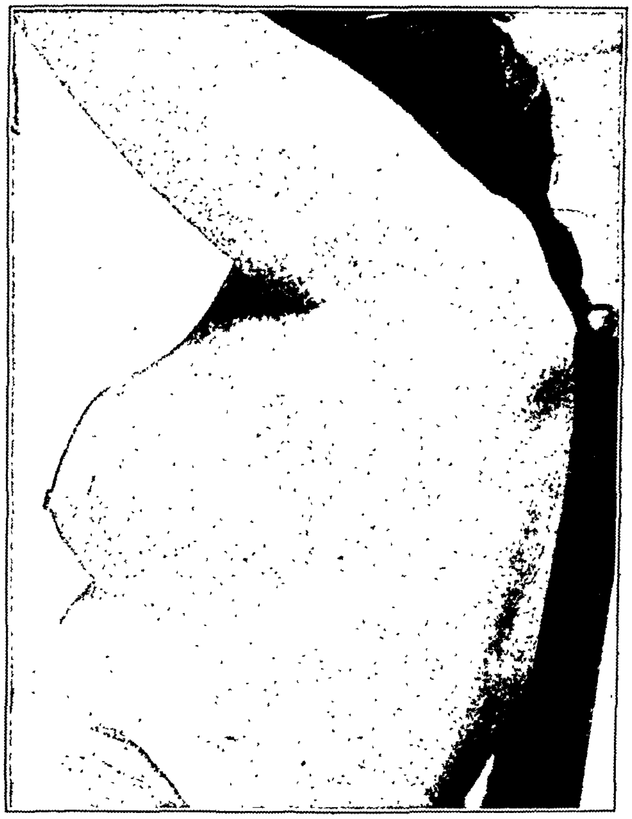

Fig. 2.—Side view of growth shown in Fig. 1.

first suggested been generally adopted instead of calling the disease by the name of one who so accurately described it.

Cancer and abnormal involution are the two most common diseases of the breast, as will be seen by an analysis of two hundred of my consecutive private cases (Table 1).

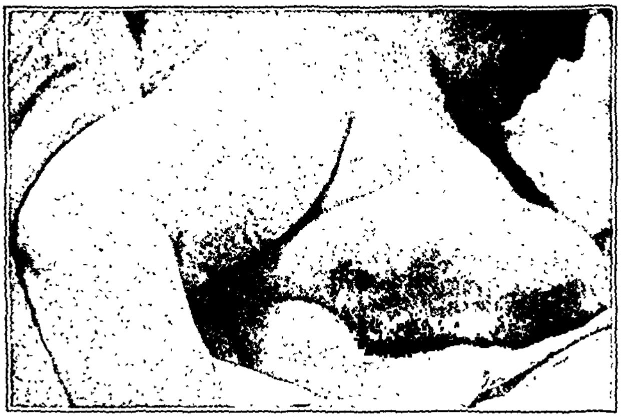

Fig. 3.—Ulcerating tumor.

TABLE 1.—DISEASES OF THE BREAST IN TWO HUNDRED CASES

	Number	Per Cent.
Carcinoma	83	41.5
Abnormal involution	67	33.5
Benign tumors	30	15
Papillary cyst adenoma	6	3
Tuberculosis	6	3
Sarcoma	5	2.5
Galactocele	3	1.5
Total	200	100

If we add the six cases of papillary cyst adenoma to the sixty-seven of abnormal involution we have seventy-three so-called benign cases and eighty-eight malignant ones in a series of two hundred. Hence they are about equally common. The potential malignancy of papillary cyst adenoma is much greater than that of abnormal involution, as the tumors in five of my six patients showed marked cancerous degeneration. In fact, I no longer consider this disease as benign. That it begins as such is true, perhaps, but it so quickly tends to assume a malignant phase that it is safe only to consider it as malignant and to treat it in the most radical manner. The same is equally true of Paget's disease. The eczema of the skin is the secondary manifestation of duct cancer and is due to the irritating discharge from within the ducts. The proof of this is found in the fact that the deeper we go, the more marked evidence we have of malignancy, whereas, if the superficial condition were the original one the reverse would be true. Thin, Raymond Johnson, Williams and others were fairly prompt to controvert the views of Sir James, but the latter's more commanding position and his forceful presentation of his case caused his view to be accepted as an ex-cathedra utterance.

How is cancer of the breast to be treated? Understanding as we now do, that it is strictly a local affection primarily, the answer should always, and without exception, be as direct and positive as language can make it. Free and early excision by the knife is the only thing to be considered, because one can never tell the extent of the disease until the lesion and surrounding tissues have been examined by sight, touch and the microscope so that the surgeon may know that his work has been rightly and thoroughly done. Hence the utter futility of caustics, radium, Roentgen rays, etc. There are conditions less pitiless and destructive in their nature in which second- and third-best remedies may be used if, through a fancied dread of a surgical operation, the patient insists on them. But cancer is not one of them, and the medical man is recreant to his trust if he does not protest against a course which means almost certain disaster. The danger of an operation at this time is, at the most, one-half of one per cent., and if performed early nearly all will result in a permanent cure. Even when cancer has been present for a year the chances of success are about equal. After more than a year's duration one-third, one-fourth or less will be cured, according to the extent of the growth, its location, the age of the patient and other circumstances. Can more reasonably be expected of any treatment for a disease that will almost certainly prove lethal in thirty-six months without treatment? *Cancer is curable and its existence in the breast*, or other external organs, should, from its very nature, be evident quite soon; therefore the responsibility for so many deaths (18,000 annually from cancer of the breast in the United States[1]) rests with the hesitating hosts or the equally dilatory physician who is first consulted. It is no fault of the cancer, for there is visible evidence of its presence long before it has ceased to be a local and removable enemy. But both patient and physician may answer, "Yes, I knew there was a tumor present, but did not suspect that it was serious." Lumps or tumors of the breast are always serious and presumably malignant until the contrary is established, for I have shown that of 200 of my private patients taken consecutively, 161 were either malignant or potentially so. Add to them the six cases of tuberculosis, in which it is almost as necessary to have a radical operation, and the number is increased to 167. With such melancholy facts staring one in the face, why will women and their family physicians continue to act as little children who play with fire? It passeth all understanding, yet they do. Those who act promptly are as the wise, those who are tardy as the foolish virgins. Does not the drowning person catch at anything, even straws, before going down? But the victims of early cancer have a life boat into which

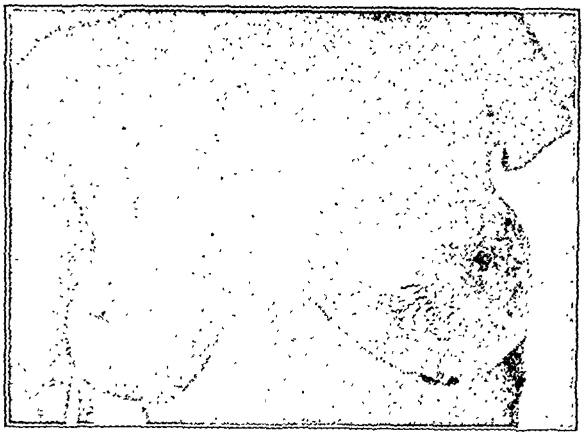

Fig. 4.—Sarcoma.

---

[1] There were 75,000 deaths from cancer, and it is customary to estimate that 25 per cent. approximately were due to mammary carcinomas.

they may enter at any time, yet they sink. We must be patient with them, for the same persons have been both blind and deaf to the progress of medicine in many other directions, as they have refused to allow their children to be vaccinated, denied them antitoxin when stricken with diphtheria, declined a timely operation in appendicitis and strangulated hernia, even refusing, though abundantly able to give them everything that wealth and supposed enlightenment offers, any medical treatment at all. Education! education! education! must be given them, and it is our solemn and bounden duty to give it. They may reject our advice and run after false gods once, but a single lesson should suffice.

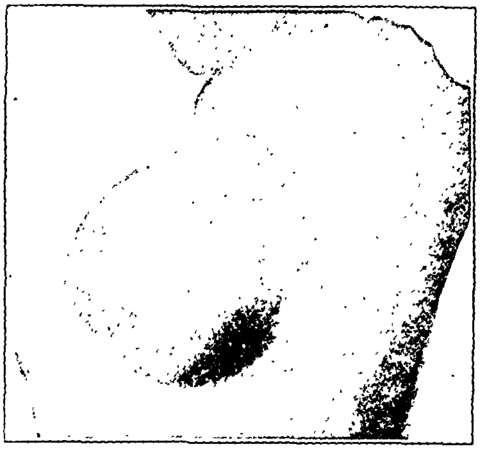

Fig. 5.—Sarcoma.

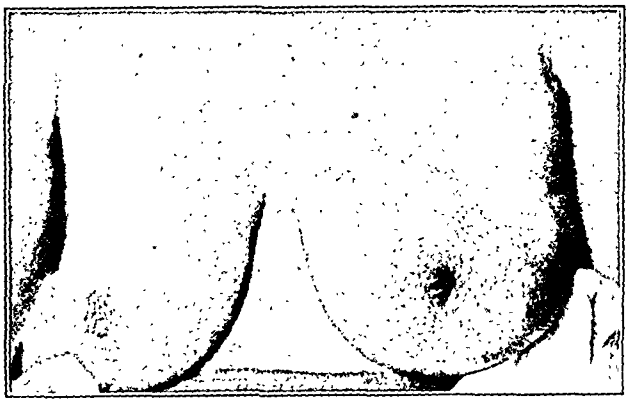

Fig. 6.—Paget's disease.

I have spoken in a general way of the benefits of early operation and the hazards of delay. Let me now be more specific and speak of results in average cases, taking them as they present themselves to surgeons for operation, some of them coming early, some fairly early, others late, and others still very late. Private patients, being more intelligent and having the ability to seek timely relief, give us much better results than are found in those whose lives are a constant struggle with adversity. Moreover, their appreciation of the dangers surrounding them keeps them in closer touch with their medical attendants; therefore far more accurate records may be kept concerning their after-history. For this reason I prefer to limit my statistics to private patients concerning whom everything is known, even though the aggregate will be less, rather than to include many others of whom little or nothing is known. Certainly, I maintain, accuracy is best subserved by so doing. Ward patients will not, as a rule, keep in touch with the surgeon after they leave the hospital and, as I am unable to give, even approximately, the condition of many, all are excluded.

Volkmann thought that if patients were free from recurrence at the end of three years after operation, a radical cure could be affirmed. Until recently surgeons everywhere accepted the teachings of this great surgeon. It is even now customary to measure our results by this standard, though many believe, and I am one of them, that a five-year period is better, as an additional 10 per cent., possibly more, of recurrences will take place or, to speak more accurately, be manifest between the three and five year periods. It is questionable if any actually do recur after three years, but, as stated, they become evident, though hitherto obscure. For all practical purposes it is a fair rule, if we admit the few exceptions. Of fifty private patients taken consecutively,[2] thirty-six (72 per cent.) are well three or more years after operation, thirteen are dead, and one has a recurrence in the mediastinum and is, of course, counted as lost. So, fourteen are either dead or soon will be (28 per cent.). To show that I have not picked my cases, the woman living with a recurrence (Figs. 1 and 2) was operated on Nov. 11, 1911, before a number of surgeons attending the Clinical Congress in Philadelphia, and it was stated that she had been refused operation by a prominent surgeon of Philadelphia on the ground that her case was inoperable. There has been no recurrence *in loco*, which shows that the growth in the breast was not inoperable. Mediastinal symptoms were not present until nearly three years after operation. Of these fifty cases there were six with such extensive axillary involvement that I was compelled deliberately to resect the axillary vein to get rid of all apparent disease and make a thorough axillary dissection. In ten of them the subclavian triangle was explored (on account of high axillary involvement or peripherally lying tumors), though most of them were found to be without disease. I have never cured a patient with supraclavicular involvement. I do not consider it as necessarily an inoperable condition as others (Johns Hopkins and Massachusetts General hospitals) report undoubted instances of cure. It is a distinctly unfavorable omen and was universally considered as a barrier to operation until Halsted proved by his results that it was not. Two of my patients had ulcerating tumors, and one of these had been denied operation by another surgeon. This woman lived more than six years without the slightest evidence of recurrence, and finally died of paralysis at the age of 72 (Fig. 3).

A summary of the thirty-six living patients shows that operations were performed as indicated in Table 2.

TABLE 2.—SUMMARY OF OPERATIONS ON THIRTY-SIX PATIENTS LIVING

Year	Number	Months
1899	1	January
1900	2	May, December
1901	1	October
1904	3	July, September, December
1905	4	September, 2; November, 2
1906	6	February, 2; July, 1; September, 3
1907	1	December
1908	4	March, May, October, November
1909	2	April
1910	6	January, April, June, July, November, December
1911	6	January, 1; April, 2; October, 2; November, 1

There are seven who have passed the ten-year period, twenty-four who have gone five years, thirty, four years, and thirty-six three years. In nearly all of them the functional use of the arm is as good as it ever was. A few of the earlier ones who were grafted show slight impairment due to a contraction of the skin. In none of those operated on since 1906 by the method I now employ is there either impairment of function or edema. Loss of both pectoral muscles does not in the least curtail the usefulness of the arm.

---

[2] Three cases of acute carcinomatous mastitis are excluded; all were quickly fatal. I now believe the condition inoperable.

None of the cured patients operated on prior to 1909 (twenty-four) were given a course of Roentgen-ray treatment subsequent to operation, it being reserved for those with recurrences. Latterly I have secured, through the cooperation of my colleague, Dr. Pfahler, results which warrant its employment in the more advanced cases. In those of average severity, also, unless I feel satisfied as to the thoroughness of removal, it is employed. In early cases I can see no reason for its use. In several very advanced cases I have been inclined to give at least a part of the credit to Roentgen-ray treatment subsequent to operation. One such patient from Atlantic City was operated on in July, 1910. I did not believe that she would live a year. At my request, she was reexamined, along with nearly all of the cases here reported, November, 1914, and was examined also by a number of visiting members of the American College of Surgeons. She is absolutely well in every way.

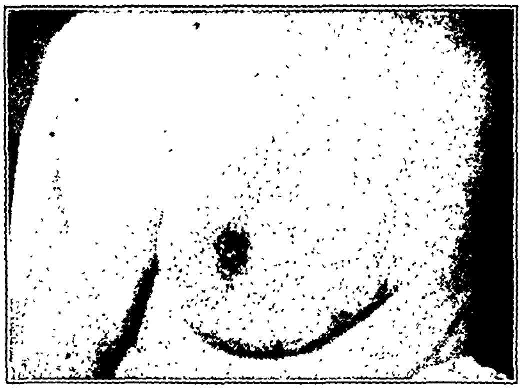

Fig. 7.—Paget's disease.

Since March, 1913, at least three patients operated on were so advanced that the Roentgen rays were sent into the wounds in great concentration before they were sutured, as no hope of a radical cure was entertained in any of them. One, with a very large sarcoma, died in six months (Figs. 4 and 5).

One, a case of Paget's disease (Figs. 6 and 7) with one of the very worst axillas I have ever encountered, showed a recurrence in the neck in thirteen months. The neck had been explored at the time of operation with negative result. This woman, who is alert and of quick perception, assures me that she consulted me two weeks after she noticed the inflammation and ulceration around the areola and nipple. She could not have suffered from cancer less than from eighteen months to two years, and this statement was made in my notes taken the day she came to me from Wellsboro for operation. She had no pain or other symptom, and believed herself to be well until the trouble with the nipple and areola began; and it was for this that she first consulted Dr. Longwell, and not for the cause of it. It proves that the affection of the nipple and areola is usually a secondary or terminal process, as I have always maintained.

The third patient to receive Roentgen rays into the wound before suturing is apparently well in every way more than fifteen months after operation. She was also examined, this month, by a number of visiting surgeons and myself.

But, grateful as I am for the assistance of the Roentgen rays or any other agent in combating so protean an affection as cancer, I wish to state most positively that they have no place in the treatment of cancer of the breast *until after operation.* They will cure epitheliomas of the skin and superficial sarcomas which may be inoperable. This I have witnessed more than once. But I have yet to see a single patient with mammary carcinoma passing the three-year limit in whose case the credit could fairly be given to Roentgen rays. They are in my judgment and experience much better than radium, as the only two patients I have submitted to the latter treatment were unquestionably made worse by it and quickly succumbed. This was their opinion and it is mine.

To treat an operable neoplasm of the mammary gland by either electricity, radium or Roentgen rays has no justification whatsoever, pathologic or clinical. We have heard entirely too much of radium and its marvelous cures and have had too little verification of its beneficent powers. Whatever it will do, Roentgen rays will do better. The latter are available to poor and rich alike, while only the wealthy can afford to travel in their private cars across the continent chasing this *ignis fatuus.* The German surgeons have tried it out, abandoned its use, and warned the public against it. The storm in America has about passed, the air has been clarified, the damage estimated, and, like lightning, it has struck in only a few high places.

2106 Walnut Street.

BUYO CHEEK CANCER

WITH SPECIAL REFERENCE TO ETIOLOGY *

GEORGE G. DAVIS, A.B., M.D.
Associate Professor of Surgery, University of the Philippines
MANILA, P. I.

In my early work at the Philippine General Hospital, Manila, I was impressed with the frequency of cheek cancer in women, and also with the almost universal habit in elderly persons of chewing buyo. The possibility of buyo as an etiologic factor in mouth cancer occurred to me, and accordingly I have studied all the cases at my disposal and reviewed the histories of all cases of mouth cancer that are recorded at the Philippine General Hospital.

The histories which I reviewed are of patients who were under the care of Drs. John R. McDill, P. K. Gilman, R. Rembe, Hans Ernst Schiffbauer and of patients from my own service. The photographs for the most part were made by the Bureau of Science.

In presenting this paper, I wish first to discuss in some detail the various constituents of the buyo chew; secondly, to discuss the prevalence of the habit and customs in connection with it, and thirdly, after presenting the cases in a more or less outline form, to consider the essential findings in these cases and draw conclusions from the data hereinafter given.

The name "buyo," which is commonly used and applied to the "chew" that is indulged in, is not in all cases strictly definite, as the constituents of the combination are generally four in number: the buyo leaves, the betel-nut, slaked lime and tobacco.

---

* Read before the Manila Medical Society, March 2, 1914.

It is true that the buyo leaves alone at times are chewed, but this is probably not from choice but rather because of lack of opportunity to obtain the other principles, or because of insufficient funds to buy them. So in this paper, when the term "buyo chew" is used, it will mean, as is commonly understood, the whole: all the constituents of the combination rather than the buyo leaves alone. In India the word "pan" is similarly employed referring to the leaf alone or to the leaf with the other constituents.

THE BUYO LEAF

The botanical name for the buyo leaf plant is *Piper betle,* Linn. (natural order, *Piperaceae*). The term "buyo" is of Visayan origin, but this is used quite commonly by the Tagalogs and other peoples of the Philippine Archipelago.

The cultivation of the betel-leaf plant is pursued with more careful attention than any other economic plant in the islands. No pains are spared in providing the roots of this plant with abundant air, water and food. Its leaves and stems are protected against insects, wind and sunshine.

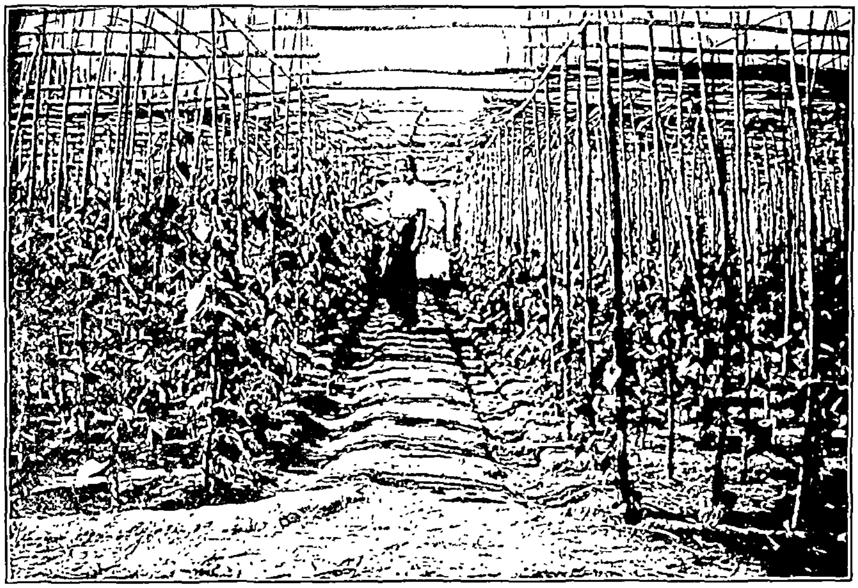

Fig. 1.—View of buyo vineyard, in Pasay, showing the careful arrangement of vines about the bamboo sticks and the cross-sticks above, over which material is placed to protect the young leaves from the hot sun and hard rains and winds; on each side of the center path are the irrigation canals. Photograph by C. H. Storms.

Many families in Pasay, Rizal Province, near Manila, make their livelihood by growing these leaves for the market. Each plant occupies an area of from 30 to 70 cm. (from 12 to 27½ inches) and one family will care for as many as 1,500 or 3,000 plants (Fig. 1).

The regulation of the water supply to the plants is important, as either a lack of or an excessive amount of water retards the growth. All the Pasay gardens are irrigated, and on days when it does not rain, water is supplied by well-sweeps. To prevent excess of water after a hard rain-storm, and during the rainy season, a trench one meter deep is dug around each plot. For the same reason, when the garden is plotted out it is arranged so that it resembles a gently sloping roof; the ridge at the center of the plot runs the entire length and is about 25 cm. (10 inches) higher than the soil along the two lower edges. In some plots the soil slopes in but one direction. In others, however, the two halves of a plot slope toward each other.

A porous soil is best suited as it allows free circulation of both air and water, which promotes rapid root growth and in turn rapid growth of stems and leaves. Impervious soils are made porous by addition of sand, lime and decaying vegetable matter.

As the vines mature the stems are tied to bamboo sticks which are about 3 meters (10 feet) high. The bamboo sticks in each row are firmly tied to a long bamboo strip that runs the entire length of the row, 2 meters (6½ feet) above the ground. Other cross-pieces of bamboo are placed 60 cm. (2 feet) apart and firmly tied to the long strips. Over these cross-pieces a few banana and palm leaves are usually laid to protect the tender leaves from the sun, as properly shaded vines produce the more desirable larger and thinner leaves which bring a better price in the market. Protection from objectionable winds is obtained by surrounding the plot with a jungle growth of coconut and bamboo trees, and banana or other plants.

There are three varieties of betel leaf: the Sañghilo, the Pula and the Kinalabao. The Sañghilo has hard, dark leaves. The Pula are large, pale, green leaves which are very tender and more highly priced than the dark green leaves of the Sañghilo. The Pula plants are delicate and will not produce larger leaves unless fed and watered regularly. The Kinalabao plants produce many large, coarse, fibrous leaves which are less desirable and usually not for sale in the market, unless the Pula happen to be very expensive on account of a short crop.

The desirable leaves on each plant are gathered once a week. When the terminal leaf on a stem is from 6 to 8 cm. (2⅓ to 3 inches) long, the second and sometimes the third leaves on that stem are ready to be pinched off. Each week a plant supplies from five to eight leaves. At wholesale prices one centavo (one-half cent, gold) is paid for from four to fifty good leaves. In rare instances 100 leaves bring but one centavo. In the market the leaves are assorted and divided into first, second and third class. The first-class leaves are the larger, wider, tender, pale green leaves and are sold two for one centavo. The second class, which are not so wide and are tougher, are sold five for one centavo. The third class or least desirable are sold at the rate of seven for one centavo.

In India betel leaves are chewed either in their natural green condition or after they are bleached by placing them in baskets where they are kept damp and dark for from eight to twenty days. Bleached leaves are usually worth three times as much as green ones. The essential oil is the constituent which gives the leaves their value. Green leaves contain about 1.23 per cent. of essential oil and bleached ones from 4 to 5 per cent.

The leaf is considered of value also for its therapeutic properties. In India the midstem of the leaf stripped of the leaf proper is inserted into the rectum of constipated children. In the Philippine Islands it is used extensively as an application to superficial ulcers, wounds, inflammation, etc.

THE LIT LIT VINE

When the buyo leaves are not obtainable the lit lit leaves (Fig. 2) are used as a substitute. This vine is easily grown and demands but little attention. The leaves, however, are not so desirable as they are rather tough and are not used when the buyo leaf can be obtained.

THE BETEL-NUT

The betel-nut, which is an important constituent of the buyo chew, is the fruit, or as it is popularly termed, nut of the areca or betel-nut palm (Fig. 3). The proper botanical name of this palm is *Areca catechu,* Linn.; *Palmaceae.*

The palm has a straight cylindrical stem from 12 to 15 meters (40 to 50 feet) high, at the top of which branch many graceful, long, gently curved palm leaves. The nuts are in clusters at the level of the junction of the palm leaves. When fresh picked they have a tough, shiny skin-like husk or covering (Fig. 4 *a*) which, when the nuts are dried, becomes loose and separates into fine tough thread-like fibers (Fig. 4 *b*).

The husked nut itself (Fig. 4 *c*, *d*) is conical and of dense, solid consistency throughout and cuts with considerable resistance.

The nut is rich in tannic and gallic acid, and the young nut on account of its astringent property is used to check diarrhea and in cases of superficial ulcers. In India the unripe nuts are viewed as a laxative and a carminative, and a paste is made of the powder of the dry or burnt nut and is used as a dentifrice. In Europe the ripe fruits have been employed as an anthelmintic and astringent. Most writers affirm that occasionally the nuts (especially when eaten fresh) are found to possess intoxicating and poisonous properties. This is believed to be an accidental peculiarity of certain trees. This poisonous property has been ascertained to be destroyed by boiling, and hence, no doubt, the custom has come into existence of preparing the nuts for market by various methods of cooking.

Fig. 2.—A lit-lit vine and a native nipa shack. This leaf is sometimes used when the buyo leaf cannot be obtained. The vine is more easily grown and more rugged, but the leaf is not so desirable, as it is rather tough. Photograph by the Bureau of Science.

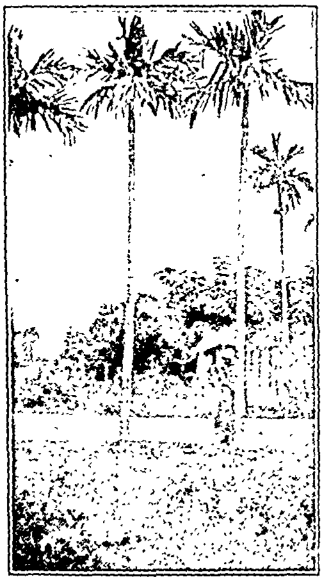

Fig. 3.—A group of betel-nut palms, growing in Pasay, Province of Rizal, near Manila. Photograph by the author.

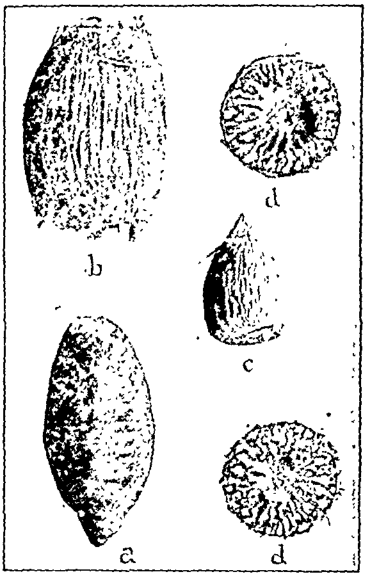

Fig. 4.—The betel-nut; showing (*a*) the newly picked nut with smooth shiny husk; (*b*) the dried nut with ragged shreddy husk; (*c*) the nut husked and (*d*, *d*) the nut in cross-section.

The powdered seeds have also long held some reputation as an anthelmintic for dogs, and areca has now been introduced into the British Pharmacopeia on account of its supposed efficacy in promoting the expulsion of the roundworm (*Ascaris lumbricoides*).

Commercially it is used in making a red dye by boiling with lime.

Lime is a regular ingredient of the buyo chew, and is spread on the piper betel leaf (Fig. 5) before it is folded and wrapped about the disk of nut. The purpose of the lime is to give a pleasant, sweet taste to the chew, which, when taken without the lime, is bitter and not so desirable. It also has a chemical action on the betel-nut and leaf which produces the red color and dyes the oral mucosa red and the teeth black.

The lime is carried in one of the compartments of the buyo boxes which are so extensively used by the Moros. The inroads that are made on the brass compartment by the lime is more than a gentle suggestion that here we have a clue to the source of irritation which produces the lesions so frequently found in the cheek.

The lime is obtained from sea shells. The shells are burned, thus driving off carbon dioxid from the carbonate, and calcium oxid or quicklime is produced. This quicklime is mixed with water which it readily absorbs, and slaked lime or calcium is produced.

In the markets, this slaked lime wrapped in banana leaves (Fig. 6) is sold, and a small handful of lime brings one centavo. The lime obtained from shells is objected to, however, as a part of the buyo chew, by certain Hindus, on the ground that it is derived from animals.

Tobacco leaves have long been a constituent of the buyo. Before the American occupation of the Philippines, plug tobacco was seldom, if ever, used. Now the buyo is flavored by an accompanying chew of American plug cut tobacco or a native tobacco, which though put up in the shape of a cigar, is in reality a plug cut (Fig. 7).

The leaves are cut longitudinally into three parts (Fig. 5), on one of which is placed a smear of lime. These three pieces of the leaf are now folded together containing the lime and are ready to be wrapped around a disk or cross-section of the betel-nut.

For additional flavor other substances such as cloves, cardamom, nutmeg or camphor are also sometimes used.

Since the introduction of plug cut tobacco into the chew, dating from the time of the American occupation, plug cut chewing tobacco has been popularized. Statistics have been quoted showing the growing preference of Filipinos for chewing tobacco rather than buyo. Recently, however, an amendment to the internal revenue law of the Philippine Islands has placed a tax of 48 centavos per kilogram on chewing tobacco. This is 33 per cent. higher than the tax imposed in the

United States. A member of the legislature is reported to have given as his reason for the higher tax that the people could use buyo.

Elderly persons who have acquired a taste for chewing buyo, but are no longer able to masticate the hard nut because of loss of their teeth, have a special method of preparing the chew. A contrivance known as the "calicut" is employed. That is, a disk of hard wood is placed within and at the node, or transverse portion, of a hollow segment of bamboo stick. Then within the hollow bamboo are placed buyo leaves, betel-nut and lime, and these are minced into fine particles by a flat spatula-like knife. This forms a pulp or paste-like mass which is then chewed. The old men carry the calicut around with them in their belts, and when they desire a chew it is prepared fresh each time. The calicut of the wealthier class is frequently made of silver.

HISTORY OF THE CHEW

The habit of chewing buyo, or "pan" as it is called in India, has been a custom with oriental tropical people for many centuries. It is estimated that one-tenth of all the people on the earth chew this mixture. Sir George Wat[1] writes:

> From the most ancient times the presentation of pan has been the polite termination of ceremonial visits. . . . The name "betel" or "betle" is Malayan in origin and simply means "a leaf," and came to English through Portuguese *betre*. The best-known vernacular names for the nut are supárí, hopárí, gua, gaya, kasaile, mari, tambul, pokavaka, oka, kamugu, adike, kunsi, etc.
>
> It would seem that the earliest historic reference by a European to the habit of chewing betel-nut occurs in the writings of Marco Polo (1298 A. D.). "All the people," he wrote, "have the habit of keeping in the mouth a certain leaf called tembul." Subsequently Vasco da Gama (in 1498), Verthéma (in 1510), Barbosa (in 1516), Garcia de Orta (in 1563), Acosta (1578, 1594), Abul Fazl (in 1590), Linschoten (1598), François Pyrard (1601), Roe (in 1615), Jacobus Bontius (1629), Bernier (1656-68), Boym (1656), Vincenzo Maria (1672), Travernier (1676), and Catchpoole (1703) (cf. Yule, Diary of William Hedges, ii, 331), all give similar accounts. Adams in his translation of Paulus Aegineta refers to the betel-nut as introduced to materia medica by the Arabs. He quotes amongst others the passages referring to it from Avicenna, Haly-Abbas, Abn Baithar, Elmasudi, Serapion and others. Abn Baithar says that it is the fruit of a palm, and observes that it is a gentle purgative, makes the breath fragrant, is a cordial and strengthens the gums and teeth. Linschoten remarks that "the Indians goe continually in the streets and waies with bettele or bettre and other mixtures in their hands, chawing, especially when they go to speake with any man, or come before a great lord." Abul Fazl apparently never saw the palm growing, since he likens it to a cypress tree that in the wind sways till it touches the ground. This circumstance may be accepted as showing that from very ancient times, as at the present day, the nut has been carried to regions remote from the areas of its production. Numerous publications have appeared within the past century that deal with the betel-nut, as met with in India.

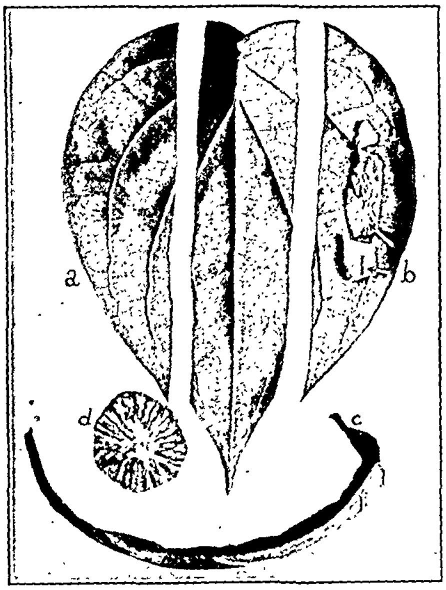

Fig. 5.—Cut betel leaf, lime and a disk of betel-nut. In preparation for chewing, the betel leaf (*a*) is cut longitudinally into three pieces; the lime (*b*) is placed on the leaf; the three pieces of leaf with the lime are folded longitudinally on themselves (*c*) and this is wrapped about a disk or cross-section of betel-nut (*d*).

Fig. 6.—Slaked lime, made from sea shells, and wrapped in banana leaves, as sold in the Manila market for one centavo.

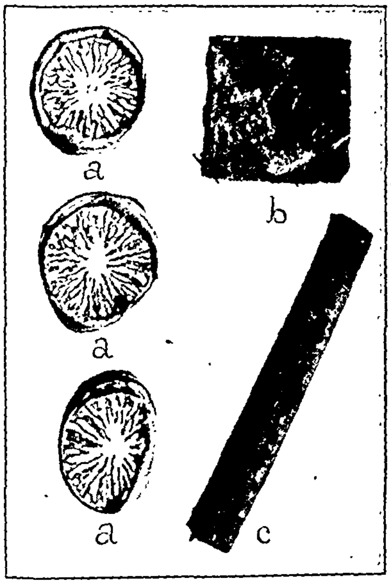

Fig. 7.—Showing (*a*, *a*, *a*) the various ingredients combined and the "chew" ready to be introduced into the mouth where it is generally held between the cheek and the teeth as one holds a chew of tobacco; (*b*) a piece of American plug cut tobacco and (*c*) a plug cut of native tobacco, one or the other of which is generally used to flavor the chew.

In the Philippine Islands and Zulu Archipelago, the buyo is almost universally chewed by adults and often by children of tender years. I have seen it used extensively in different parts of the Island of Luzon, Island of Samar, Island of Cebu, Island of Iloilo and in Parang, Zamboanga and Jolo, and by the Moros on the Island of Mindanao.

It has been estimated that 90 per cent. of the elderly persons in the islands chew buyo.

In Jolo I had the opportunity of an interview with the Sultan of Zulu. In regard to chewing buyo and its causing cheek cancer, the sultan stated that all the Moros were great buyo chewers; that among these people he himself had often noted growths on the inside of the cheek; that they never became cured of these growths and that he also believed that chewing buyo caused it. The sultan himself is an inveterate

buyo chewer, and as he conversed, frequently used a beautiful colored glass cuspidor, placed on his desk, to expectorate into.

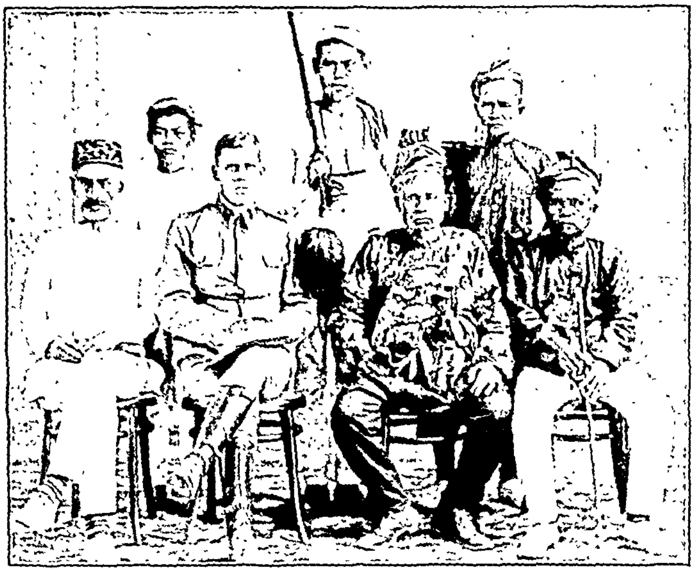

Fig. 8.—A Morro datto (chief) and staff, showing the buyo carrier in back row to the right with a large box. The officer in uniform is a captain in the constabulary. The buyo is carried as commonly in the islands as cigarets and cigars are in the United States. Photograph by the Bureau of Science.

The buyo boxes carried by the Moros are of various sizes, shapes and material. Boxes are made for individual use which are carried around by the owner slung over his shoulder by a chain or cloth handle, or bound to the body by a cord about the waist. Larger boxes are used at home and passed about by a buyo carrier when the buyo is offered to company. A buyo carrier is a part of a Moro datto's (chief's) retinue (Fig. 8). The women, who are possibly greater chewers than the men, also have buyo boxes and buyo carriers (Fig. 9).

The boxes are made of brass and frequently inlaid with silver, which is mostly obtained by melting and hammering out old Spanish coins.

In reviewing my series of 49 cases of cheek cancer, I find a positive history of chewing buyo in 40, or 81 per cent. In no case is there a history of not chewing buyo. In only 9 cases of this series of cheek cancer does it remain a question whether the patients did or did not chew it.

The length of time these patients had been chewing buyo before the growth appeared varies from three years, the shortest time, to sixty years, the longest, or an average, when we had this question of time definitely answered in 17 cases, of thirty-five years.

It occurs in women more frequently than in men. Of 49 cases, 34, or 70 per cent., were in women. The women chew buyo more than the men.

It is essentially a sickness of advanced years; the youngest patient was 23 years old and the oldest 86. The average age of forty-nine patients is 52 years. Of the forty-nine patients, thirty-three, or 67 per cent., were married; fourteen, or 30 per cent., widowed, and two, or 4 per cent., single.

In twenty cases, that is, in every case in which the question was put to the patient, the site of lesion corresponded definitely to the position in which the patient was accustomed to hold the chew. The patients themselves often volunteer the information that the buyo caused the lesion and that that was the side on which the chew was held.

The lime is, I believe, the essential or direct cause. However, the chemical properties of the leaves, containing essential oil, and the chemical properties of the nut, containing tannic and gallic acid, may be predisposing factors. Sometimes a rather large quantity of lime is used, and the patient states that this causes a "burning" sensation and often irritates the cheek.

That the betel-nut is a predisposing or an accessory mechanical factor is shown forcibly in one case. This patient had previously chewed buyo, and an epithelioma of the left gum developed. The left jaw was resected by Dr. Burdette, three months before I saw her. She attributed the origin of the growth to the action of the lime in the buyo. Hence since her operation she has not used any lime whatsoever, but has chewed only the betel-nut which had been chopped up fine by the use of the calicut, as she is no longer able to masticate the nut because so many teeth are missing.

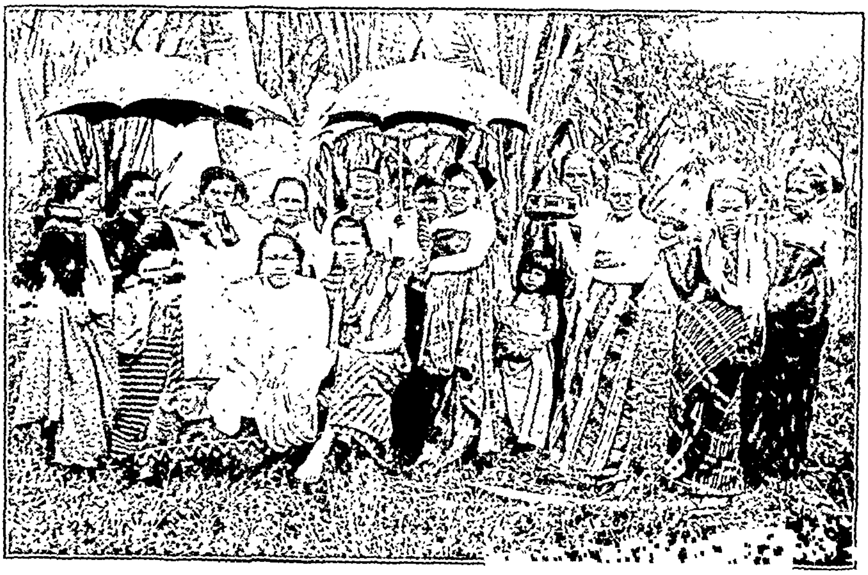

Fig. 9.—A Moro datto's (chief's) wife, her retinue a [illegible] uyo carriers, the second and the third on the right and the first and third on the left. The women are greater buyo chewers than the men. Photograph by the Bureau of Science.

In this case numerous white pin-point to pin-head sized white deposits of betel-nut pulp are scattered over the mucous membrane of the lower lip and the gum of the mandible and the roof of the mouth, and hard and soft palate. When these white areas are scraped from the mucosa, a small bleeding ulcerated area results. Thus we see that the betel-nut may aid or prepare in a mechanical way an ulcerated area for the chemical action of the lime.

The clinical history of the patients suffering from buyo cheek cancer are strikingly similar. The first symptom the patients note is an involvement of the inner aspect of the cheek. This is constant and true of all the cheek cases. At first a small elevated growth in the mucosa of the cheek is noted (Fig. 10). Early ulceration of the growth is complained of, and sometimes the patients state that the growth began as an ulcer. Pain is a constant symptom and is frequently slight and confined to the site of lesion itself, but often accompanied by a severe pain of a referred type, radiating to the angle of the jaw or parotid and submaxillary regions. A burning sensation is at times complained of.

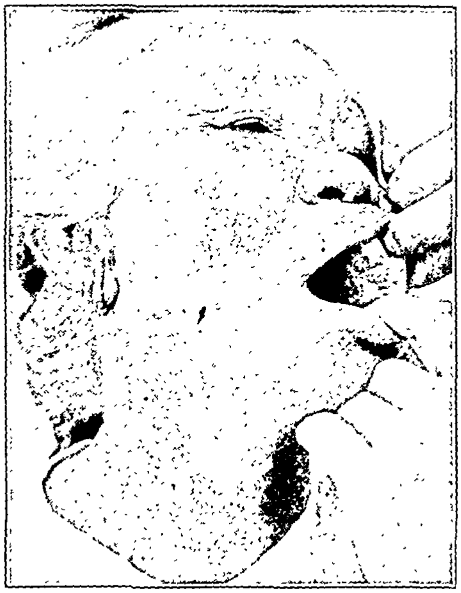

Fig. 10.—A case of buyo cheek cancer.

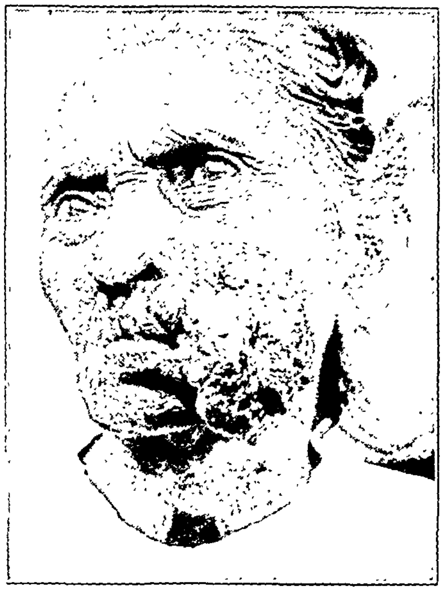

Fig. 11.—A case of buyo cheek cancer.

The growth of the tumor progresses slowly, takes on a cauliflower-like shape and soon projects from the mucosa into the oral cavity between the two rows of teeth, making mastication painful and often impossible.

Abscess formation in the tumor mass is a frequent complication, and when this ruptures spontaneously sinuses may result opening either externally or internally, or both. A foul, disagreeable odor is present in these cases.

Bleeding occurs frequently when the growth has become enlarged and fungus-like, as the growth is readily irritated by the teeth and food and by the movement of mastication or by being touched during examination.

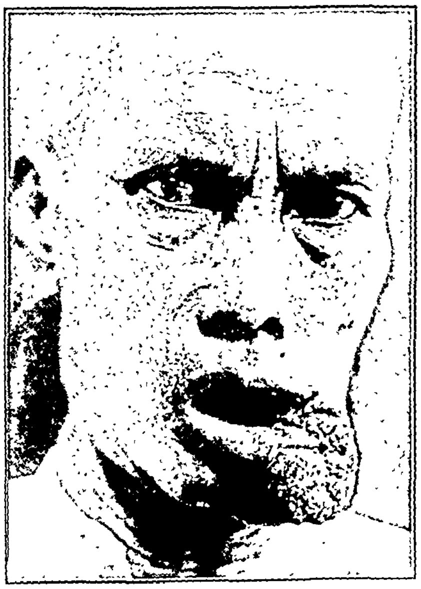

Fig. 12.—A case of buyo cheek cancer.

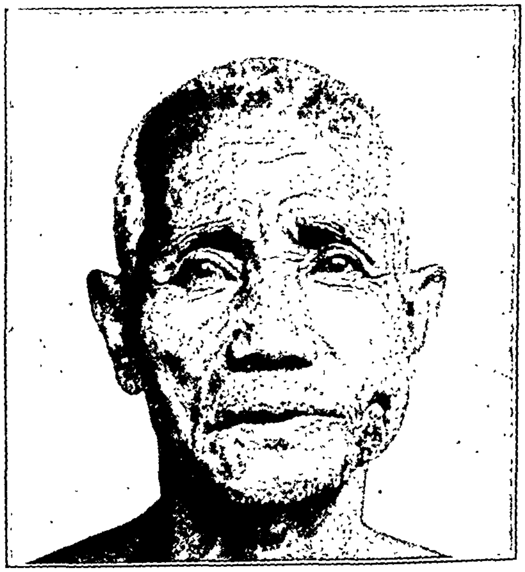

Fig. 13.—A case of buyo cheek cancer, showing the extension through the cheek.

The mucosa of the lips, tongue and entire oral cavity is colored a bright red and the teeth a dark brown or black by the buyo. The teeth in the region of the growth fall out early as the extension of the growth from the cheek to the neighboring gums proceeds.

From the initial lesion in the mucosa of the cheek the extension of the growth progresses upward, downward, posteriorly and anteriorly, and also by perforation through the cheek. Accordingly, the secondary involvement includes the upper gum, lower gum, tonsil and angle of the mouth. The outer surface of the cheek may be involved in one of two routes, namely, by extension from within from the angle of the mouth involving the cheek in a cauliflower-like mass (Figs. 11 and 12), or secondarily by perforating the cheek, the angle of the mouth not being involved (Fig 13).

The regional submaxillary lymph-glands become enlarged and indurated, but general metastasis is rare.

At my request, Dr. B. C. Crowell, associate professor and chief of the Department of Pathology in the University of the Philippines, has reported as follows on the histology of the surgical pathology specimens removed from a number of cancer of the cheek cases from my service at the Philippine General Hospital:

> Small portions of tissue from the inside of the cheek have been submitted to me for histologic examination from twelve cases, and in one of these cases a small portion was also submitted from the outside of the cheek, the lesion having been said to have extended from within outward.

Sections from these tissues have all shown the structure of an epithelioma or carcinoma originating from pavement epithelium. There has been a remarkable similarity in the general characters of the microscopic lesions in the different cases, so that a brief description of the histology of one case may be considered as applying to all cases. There is marked downgrowth of the epithelium below its normal limiting basement membrane in the form of dense strands, with a very marked tendency to the formation of epithelial pearls and apparent separation of masses of epithelium from direct continuity with that on the surface. The pearls, which form so large a part of the structure and have been seen down in the muscle tissue, are frequently almost homogeneous in appearance, having undergone hyaline degeneration or extensive keratinization. The intervening stroma occupies a relatively insignificant part, but in all cases has shown extensive round-celled infiltration. Practically all of the cases have shown a greater or less grade of ulceration, but in none of the cases examined has there been any conclusive evidence that the tumor originated on the basis of a preexisteing ulcer.

I have had the opportunity of seeing several of these cases clinically and almost all showed extensive growth and ulceration. One early case, however, was seen, which presented a circular, flat, elevated growth on the inner side of the cheek. This was pale gray in color, and its surface was smooth and glistening, with no evidence of ulceration, being apparently entirely covered by mucosa. In this case, at least, the growth apparently did not originate on the basis of an ulcer, and it is supposed that the other cases were similar in their earlier stages. This would seem to remove these cases from that large class of cases which includes those following specific ulcerations such as tuberculosis or syphilis and gastric carcinomata originating on preexisting ulcers. It would suggest that they might be added to the class of cases which follow prolonged exposure to chemical irritation such as occurs in workers in paraffin and arsenic.

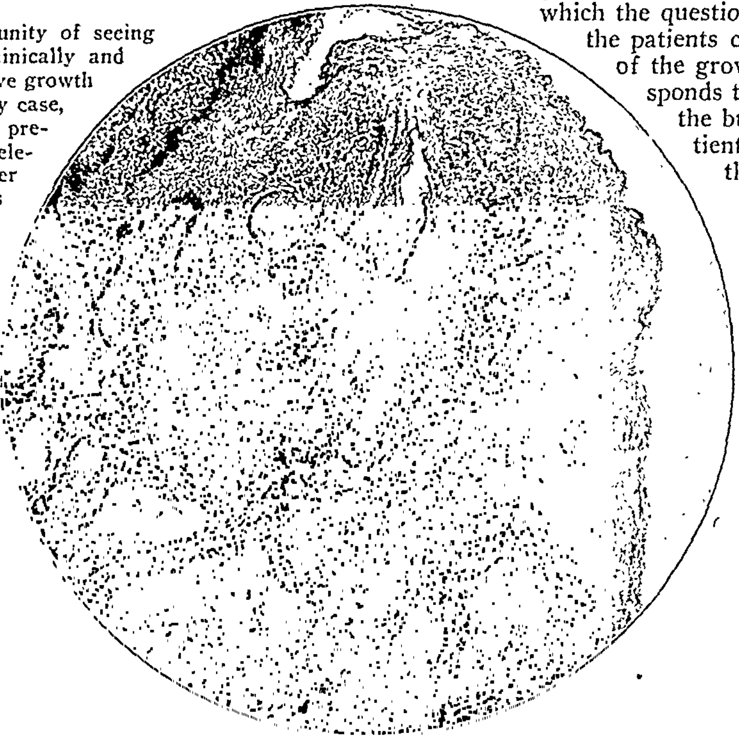

Fig. 14.—Photomicrograph of a section of tissue removed from buccal growth.

PROGNOSIS

The prognosis of buyo cheek cancer is not favorable. If not operated on, the growth becomes an enormous unsightly mass, and metastasis to regional glands occurs. The primary growth ulcerates, becomes infected, and large sloughing defects result. If operated on, the prognosis is also poor. This is because the patients do not report to the surgeon until the growth is extensive. Then a radical operation, removal of the cheek and a plastic operation from neck or forehead and scalp, is necessary. In this operation the mortality from aspiration pneumonia is high. In no case of this series did an operation give a permanent cure.

TREATMENT

The question of treatment of buyo cheek cancer is worthy of the most serious consideration. The surgical treatment is unsatisfactory. A radical or a palliative measure may be indicated. In early cases, which unfortunately are rarely seen by the surgeon, when the involvement is more or less limited and the regional glands not involved, a wide removal of the cheek and regional lymphatic glands followed by a plastic operation is the only hope of permanent cure.

If the mass is very extensive and extends into the oral cavity, between the two rows of teeth, making mastication impossible, some relief is obtained by a palliative operation, making use of the curet and electrocautery.

SUMMARY

We find, thus, cancer of the cheek as a common lesion in a country where buyo is universally chewed. It occurs more frequently in women than in men. In 100 per cent. of cancer of the cheek cases in which the question was put we find that the patients chewed buyo. The site of the growth in the cheek corresponds to the position in which the buyo was held. The patients themselves attribute the origin of growth to the chewing of buyo. In this group of seventy-five cases of oral cancer we find that forty-nine, or 65 per cent., are cancer of the cheek, a percentage found in no other than a buyo-chewing country.

Cancer of the cheek in Europe and in North America, countries where buyo is not chewed, is a comparatively rare lesion, especially in women.

In buyo cheek cancer we find a lesion which, etiologically, clinically, pathologically and from the point of view of course and prognosis, may be regarded as a definite and separate lesion having its own entity. It is as definite and constant etiologically, clinically and pathologically as are the Roentgen-ray epitheliomas, the kangri skin cancer of India, the epitheliomas of the arms of paraffin makers and the chimney sweep's cancer of England.

CONCLUSION

Cancer of the cheek, so commonly seen in the Philippine Islands, is caused by chewing buyo, and the active agent is the lime.

Buyo cheek cancer is a distinct, definite and separate disease of oriental tropical persons having an entity as definite as the Roentgen-ray epithelioma occurring on the hands of the early Roentgen-ray workers, as the kangri skin cancer of India, or the skin cancer on arms of paraffin workers and the brand cancer of cattle of the United States and the chimney-sweep's cancer of England.

Histologically, we find the picture of an epithelioma, and the epithelioma may be best classified with the group of epitheliomas known as skin cancer, produced by chronic irritation, which may be actinic, thermal, chemical or mechanical. In the case of buyo cheek cancer it is chemical, the action of the lime.

As this is a very common lesion in the Philippine Islands, and as the surgical treatment is far from satisfactory because the cases are too frequently seen too late, an educational campaign is advisable to teach the evil results of buyo chewing and to encourage a prophylaxis, to be gained by an entire stopping of the buyo habit.

Philippine General Hospital.

Do You Know Your Age and Birthday?—As an additional evidence in favor of a rapid extension of birth registration and issuance of birth registration certificates to parents, a matter of both legal and medical importance, Stiles in Public Health Reports cites instances of popular ignorance and carelessness regarding birthdays and age. He says this applies not only to families of laborers and farmers, but to educated families, professional families and leading families much more frequently than one would suspect until one attempts to gather such information. In a study of about 5,000 schoolchildren, whites and negroes, Stiles found a startling ignorance and carelessness in regard to their ages. One university graduate signed a sworn statement that he was three years younger than the records showed him to be. He did this in good faith until proof was presented. Pupils may know their age at the last birthday, but when asked the year of their birth, even high school pupils and other children in astonishing numbers give erroneous answers, nor do their parents, especially the fathers, know the date of birth of their children, according to Stiles. Stiles does not believe that this is always an evidence of mental defectiveness, and cites the instance of the university graduate referred to, but that it is a strong argument in favor of accurate registration of births.

CAVERNOUS AND CYSTIC LYMPHANGIOMA OF THE CECUM

WITH REPORT OF A CASE *

EDMUND A. BABLER, M.D.
Visiting Surgeon, City Hospital; Surgeon, Deaconess Hospital
ST. LOUIS

If Wegner's position relative to the congenital origin of lymphangioma is correct, it is not at all surprising that my review of the available literature has failed to show the record of a case of lymphangioma of the cecum or colon. With the present-day method of microscopic examination of all tumors removed at operation, surgeons have become appreciative of the importance of the method and the frequency of tumors heretofore regarded as of infrequent occurrence. It is not at all improbable that the future will show that lymphangioma of the large intestine is not so uncommon as the literature now indicates.

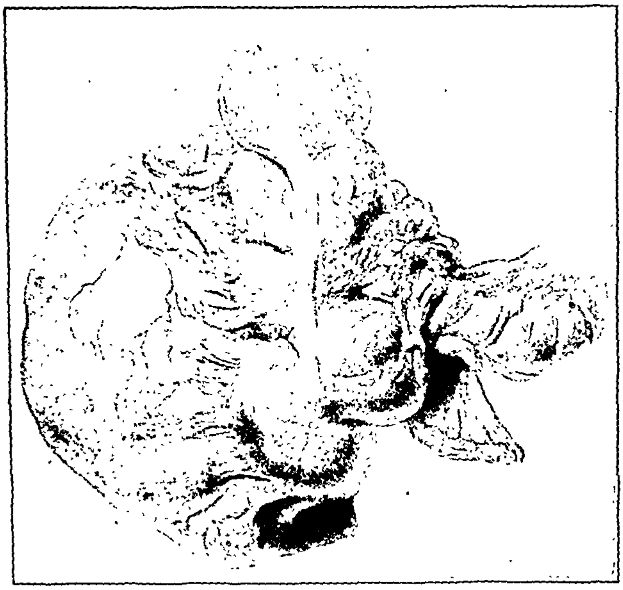

Fig. 1.—Anterior view of growth showing intimate relationship to cecum.

Wegner[1] classifies lymphangioma into (1) simple, (2) cystic, and (3) cavernous. In our specimen, Professor Welch found both cystic and cavernous forms of lymphangioma.

It is conceded by some writers that inflammatory changes may occur in these growths, and that the latter are detected in a large percentage of the cases before the patient attains the thirtieth year. In twenty-five of the fifty-two cases of lymphangioma of various parts of the body collected by Klemm,[2] the patient was under 25, while in thirty-eight cases the patient was under 40. Eleven were over 40 years of age.

Sudden elevation of temperature in cases of lymphangiomas is perhaps explained by inflammatory changes therein or by the intra-abdominal rupture of one or more of the cysts. Many of the cysts contain a cloudy substance. Kuttner[3] has discussed inflammation and pus formation occurring in lymphangioma. It is somewhat difficult to explain the inflammatory changes which have so frequently been noted in these growths. If they are of congenital origin why should inflammatory changes occur therein?

Hagenbach[4] has reported a very interesting case of symmetrical lymphangioma of the neck which was noted at birth. Thiebierge and Gottheil[5] have each reported a case of lymphangiomas of the skin, while various authors have reported lymphangioma of the mesentery, small intestine, fallopian tubes, diaphragm, etc.

The following very interesting case of cystic and cavernous lymphangioma (Welch) of the cecum is of especial interest to the surgeon in view of the fact that the clinical picture simulated so closely that of an acute infection of the appendix. It is also of interest owing to the unusual location of the growth.

REPORT OF CASE

History.—W. B., a lad aged 15, was admitted to the medical service of the St. Louis City Hospital, June 28, 1913, and on the following day the patient was transferred to my surgical service. The patient stated that previous to onset of the present illness he had enjoyed good health. His father had died from consumption and his mother and one sister were afflicted with the disease at the present time. The present illness began four days before with sudden severe pain in the region of the appendix. The pain was followed by vomiting and fever. Examination showed a pulse of 116, a temperature of 102, and a leukocyte count of 16,000. Examination showed the patient's expression somewhat anxious, the abdomen slightly distended in the region of the appendix, and considerable tenderness and rigidity in the region of the appendix. There was no enlargement of the inguinal glands. The left side of the abdomen did not show rigidity. Rectal examination failed to show a mass. A distinct mass however, could be outlined about an inch above and an inch and a half anterior to the superior spine of the ilium. The patient's right limb was retracted. The patient presented all the symptoms and signs of an acute infection of the appendix with abscess formation.

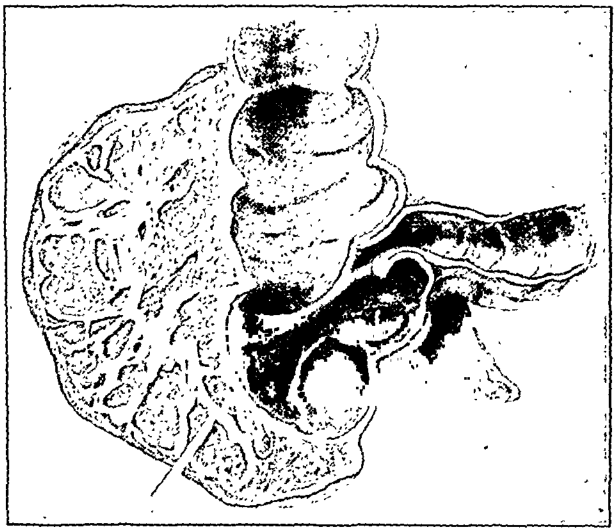

Fig. 2.—Longitudinal section of tumor and cecum.

Operation.—Immediate operation was performed. When the abdomen was opened through the usual incision along the border of the rectus muscle, a firm mass about the size of a man's fist was found situated to the outer side of and intimately connected with the cecum. The appendix was free and did not show evidence of inflammation. The mesentery glands were not enlarged. The growth was almost entirely covered with peritoneum. The cecum did not show infiltration or inflammatory change. There was no evidence of tuberculosis.

The diagnosis of probable carcinoma of the cecum was made, and the cecum with the entire ascending colon and about 8 inches of the ileum were excised, and a side-to-side anastomosis by means of a Murphy button was made. The button was expelled on the seventh day, and the patient made an uninterrupted recovery. The patient was discharged, July 10. He is alive and in apparent perfect health at this time.

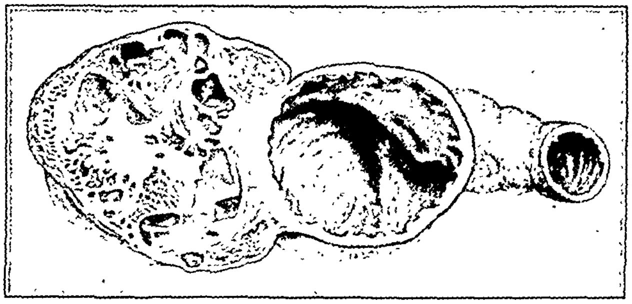

Fig. 3.—Transverse section of specimen.

Dr. F. B. Hall made a roentgenogram of the colon and terminal loop of the ileum, showing the present condition of the anastomosis.

PATHOLOGIC REPORT BY PROFESSOR WELCH

The specimen consists of a portion of the intestine with a tumor attached to the intestinal wall—hardened in alcohol. The intestine is the lower end of the ileum, 14 cm. in length, and the cecum 9 cm. in length, with the appendix. Partly enveloping the cecum and growing from its outer wall is a tumor measuring approximately 10 cm. in length (parallel with the axis of the gut), 6 cm. in thickness and 5 cm. in breadth. The tumor is, except over a part of the area, invested with peritoneum. The shape is irregularly oval with a somewhat irregular, nodular outer smooth surface.

Upon section the tumor presents a variegated appearance and is seen to be composed of a solid part, apparently connective and adipose tissue, and of many larger and smaller cysts and channels. The cysts vary from those just visible to the naked eye to those 2 cm. in diameter. From some the contents have escaped, others contain clear gelatinous material, and others blood either fresh or altered in color. The walls of the cysts in general are thin and smooth, but some show projections and suggest fusion of adjacent cavities.

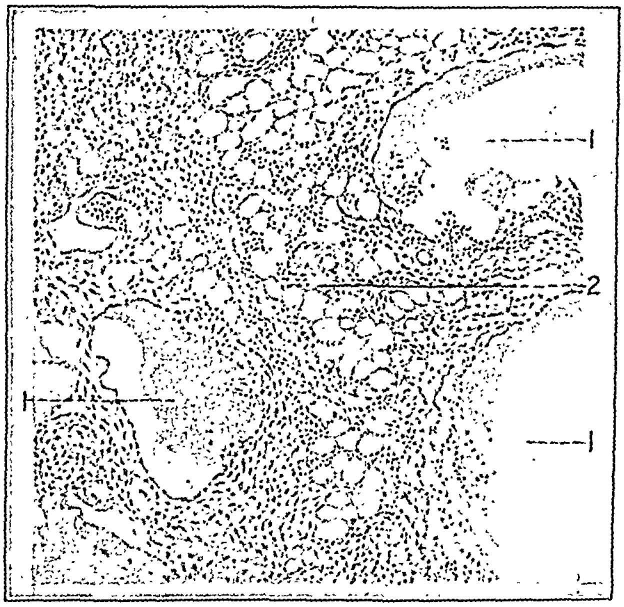

Fig. 4.—1, Lymph spaces, surrounded by edematous connective tissue (2), and infiltrating fat.

The solid tissue is in places hemorrhagic, in other places grayish and firm, or with the appearance of fat.

The tumor is intimately incorporated with the outer wall of the cecum, from which it cannot be detached. It has not invaded the mucous membrane, which is intact.

Microscopic Examination.—The cystic and canalicular spaces are seen to be dilated lymphatic vessels lined by endothelial cells. The contents vary, being sometimes, especially in the smaller spaces, homogeneous, and in others containing fibrin, leukocytes and red corpuscles in varying proportions. The leukocytes are mainly lymphocytes, and some of the lymph cavities are completely filled with these cells. Other cavities contain only or chiefly red corpuscles. The walls of the cysts and dilated vessels show bundles and detached strands of smooth muscle, often much hypertrophied.

The tissue between the cavernous spaces and channels is fibrillated connective tissue, or in places, adipose tissue. It is partly doubtless the preexisting tissue, but much of it is of new formation. In places it is delicately fibrillated and edematous; in other places more densely fibrous. A notable feature is the presence of smooth muscular cells, often hypertrophied not only in the walls of the lymphatic and blood vessels, but also scattered in the intervening tissue. Here are also fusiform and stellate fibroblasts.

Accumulations of lymphoid cells are present not only within the cysts and channels, but also in their walls and likewise in the intervening stroma. There are more or less extensive extravasations of blood, mostly fresh, both within the lymph spaces and in the tissues.

The cystic dilatations are in places so numerous as to give a honeycombed appearance to the sections; in other areas the tissue is more solid, but throughout the new growth such dilatations exist. Sections which include the junction of the tumor and the cecum show that similar, although narrower, dilatations of the lymph vessels occur in the submucous, muscular and subserous coats.

There is proliferation of the endothelium of the peritoneum, and considerable new growth of connective tissue and cellular infiltration in the serous membrane immediately adjacent to the tumor. The lymphatic vessels, frequently dilated, are filled with lymphocytes.

The same colloid or coagulated material present in the lumina of the lymph cysts can sometimes be recognized in the meshes of the tissue composing the solid part of the tumor. Fibrillated fibrin is also present in some places in the tissue.

Diagnosis.—Cystic cavernous lymphangioma.

Remarks.—To what extent, if any, there is an actual new formation of lymphatic vessels it is difficult to say. It is possible that all are preexisting or these with lymphatics formed in the new tissue. The fibrous tissue and muscular cells between the lymphatics are partly of new formation, and perhaps the tumor might be regarded as a fibromyolymphangioma, but it seems unnecessary to interpret the growth as other than composed essentially of dilated lymphatic vessels accompanied, as is usual in lymphangiomas, with some new formation of connective tissue and accumulation of lymphoid cells. New growth of smooth muscle is common in lymphangiomas, although in the present instance the development of the smooth muscle cells at a distance from the lymphatic vascular walls is a notable feature.

The most plausible explanation of this type of lymphangioma refers it to some error in congenital development.

There seems to be no active infectious inflammation, although chronic inflammatory changes are present. As regards the general interpretation of lymphangiomas as inflammatory in origin, that is another matter which relates to the general theories of this form of neoplasm. I am personally more inclined to the hypothesis of congenital origin for neoplasms of the type in this case.

There are extensive extravasations of blood, both fresh and old, but I do not regard these as essential features so far as the diagnosis of the primary condition is concerned.

Shortly after I received the foregoing report, Professor Welch wrote me as follows:

> I have examined further sections from a piece which I cut from the tumor. There is nothing significant to add. The formation of masses of lymphatic tissue, growing in a polypoid form into the lumina of some of the cysts, was more noticeable, but I think that I spoke of such lymphatic tissue in my report to you. This speaks for new formation of lymphatic vessels, but is not conclusive. In fact, in many cases it is impossible to say whether the cysts are from preexisting lymphatics or from newly formed ones, and this you will find discussed in most of the articles on the subject.
>
> The new sections show partial organization of the coagulated contents in some of the cystic dilatations. The hypertrophied muscle in the walls of the cysts and channels is conspicuous, as also are dilated blood vessels. Of course, there is a good deal of chronic inflammatory change, as I have already noted.

COMMENT

The case of lymphangioma herein reported is of especial interest to the abdominal surgeon because of its close proximity to the appendix and the infrequency of its occurrence in the colon. Hildebrand[6] has expressed the opinion that lymphangiomas are sometimes diagnos d as lipoma or fibroma.

The fact that a tumor of congenital origin may become so intimately connected to the cecum and be subjected to certain changes which manifest themselves by high leukocyte count, severe abdominal pain, vomiting, high temperature and, in fact, the usual clinical manifestations of an infected appendix, is worthy of careful consideration. Hertzler[7] and other writers have expressed the belief that these tumors are of inflammatory origin.

I am especially indebted to Dr. W. W. Grant for his interest in the case; also to Professor Opie and Drs. Thomas and Tiedemann of Washington University, as well as to Dr. Hertzler of Kansas City, for valuable assistance. My indebtedness to Professor Welch of Johns Hopkins is evidenced by his pathologic report.

THE INTRAVENOUS USE OF COLLOIDAL (GELATIN) SOLUTIONS IN SHOCK

JAMES J. HOGAN, M.D., M.R.C.S., ENG.
SAN FRANCISCO

I. INTRODUCTION

Periodically in medical and surgical practice we are brought face to face with a series of signs and symptoms that are in essence the expression of an abnormally low blood pressure, and which, when sufficiently marked, serve to kill a patient.

Not alone is the list of pathologic states in which a low blood pressure is observed very long, but the explanations given by different authors as to why the low blood pressure exists in any given state are very different. From a therapeutic point of view, however, this ground is held in common by all authors: They are agreed that a saving of life is intimately associated with, or rendered possible only by our success in raising the blood pressure, and keeping it up until such time as the patient himself succeeds in overcoming the conditions which are responsible for the low blood pressure.

Simple as it would seem to attain this end, its accomplishment practically is still a matter of debate. The problem involved is perhaps best presented if we consider the effects of simple hemorrhage. If by accident or otherwise, one of the larger vessels in man or a laboratory animal is opened, we observe following each other in rapid succession and in the course of a very few minutes all those alarming signs which reach their climax in death.

When now we try to say why this occurs, it is quickly brought home to us that the most serious mischief done by the hemorrhage does not reside in a great loss of red blood corpuscles or in a loss of certain of the chemical constituents found in the blood, say the hemoglobin or certain salts, but in a diminution in the volume of the circulating blood. The proof for such a conclusion is easily brought, for to protect or save an animal from the effects of hemorrhage it is not necessary to transfuse blood; but transfusion with water containing various salts (so-called "physiologic salt solution," "Ringer solution" or "Locke solution") may do. In fact, the dangers incident to transfusion of whole blood have made medical men in practice depend more and more on salt solutions of various kinds and less on the transfusion of blood itself.

But even though salt solutions of various kinds work excellently, they do this for only a limited time. In other words, it is too often noted that while a physiologic salt solution or a Ringer solution produces immediately brilliant results, this effect wears off in an hour or two, so that the individual who has been roused from the threatening effects of a great hemorrhage begins to sink again, and even though we repeat our injection, the improvement in patient or animal is again only temporary.

When we ask why this occurs we have no difficulty in finding the answer. The injected salt solution does not remain in the blood vessels. The evidence for this is perfectly clear. Not only does the blood pressure, which we have brought up after the hemorrhage, slowly fall again, but the fluid that has been injected appears as urine, or it is taken up by the tissues (an edema develops), or both. Clearly, if the water could be kept in the blood vessels, the temporary effects following the injection of salt solutions could be made more permanent.

This brings us to the heart of the problem. Why is a salt solution not retained in the blood vessels of an animal, or, put in another way, why does a circulating liquid like blood remain in the blood vessels? Why does blood not suffer the same fate as a salt solution and be lost from an animal as urine or be absorbed into the animal's tissues?

As is self evident, a correct answer to this question is not only of general biologic interest, but also constitutes the basis on which must be built the principles underlying the whole problem of perfusion as practiced for *any cause whatsoever in a* linical case.

The blood (or the lymph) remains in he blood vessels because it contains no 'free" water—all the water in it is held as hydration water) in combination with he colloids present here. A salt solution apidly disappears from the vascular sysem for the reverse reason, in other vords, because this does contain "free" vater.

The detailed experimental proof for the orrectness of this reasoning was brought ome time ago.[1] I review here a few xperiments which illustrate our contenions, after which I shall discuss the results vhich have been obtained in human cases n utilizing the principles learned on nimals.

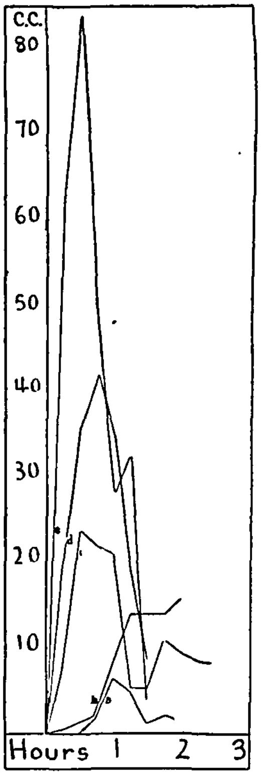

Chart 1.—Urinary secretion in a rabbit; *a*, normal; *b*, *c*, *d*, *e*, urinary secretion after injection of the same volume (125 c.c.) at the same rate of progressively more concentrated sodium chlorid solutions.

II. EXPERIMENTAL DATA

1. If we take a rabbit quietly from its age, *tie it comfortably into an animal* older and catheterize it with a small soft ubber catheter, we get a urinary secretion lat is represented graphically in the lowermost curve (*a*) of Chart 1. This, as all he other curves, is obtained by plotting time along the horizontal (in fifteen-minute intervals), and the number of cubic centimeters of urine secreted in each of these intervals on the vertical.

Let us now see what is the effect on this secretion of injecting intravenously at a uniform rate (10 c.c. every five minutes) an amount of differently concentrated sodium chlorid solutions (about 125 c.c.) which equals in volume the circulating blood in the animal. The result is indicated in the remaining curves.

In Curve *b* is shown the effect of injecting a one-eighth molecular (0.729 per cent.) sodium chlorid solution. As is readily apparent, the injection of a weak salt solution is quickly followed by an increase in the urinary output.

Curve *c* shows the effect of injecting the same volume of a salt solution that is more nearly "isosmotic" or "isotonic" with the tissue fluids of the rabbit—namely, a 0.92 per cent. sodium chlorid solution. We have no difficulty in seeing that the urinary output is under such circumstances still further increased. Also we notice that the effect of this solution on the secretion occurs earlier, even though the quantity of solution injected and the rate of injection are the same as in the previously described experiment.

Curves *d* and *e* show the effect, respectively, of injecting one-fourth molecular (1.459 per cent.) and one-half molecular (2.909 per cent.) sodium chlorid solutions intravenously. Evidently, with the injection of a constant volume of water at a constant rate, the loss of water from the body occurs the more rapidly, the higher the concentration of salt injected along with the water. Little or none of the water that is injected is retained, and if enough salt is injected with the water, even more water is lost by the animal than is injected.

Let us turn now to the interpretation of these simple experimental facts.

The whole animal, that is, all his tissues, *including the blood and lymph*, is composed of a system of colloids which under normal circumstances are saturated with water.[2] This system of colloids cannot take up any water or liberate any, except as it first suffers changes of a chemical or physicochemical character that either increase or decrease the capacity of these colloids for water. If the system of colloids composing the body is saturated with water, then clearly it cannot take up any more of this substance, and so if we inject "free" water intravenously in the form of a "physiologic" sodium chlorid solution, this cannot be retained in the body. It escapes as urine. If, instead of doing this in an experimental animal, we have employed this procedure in a patient suffering from hemorrhage, the result and the interpretation of the result are just the same. The good effects on the patient resulting from filling up his blood vessels with salt solution can be only temporary, for the water is "free" and escapes shortly after the injection as urine.

But why does a strong salt solution make the water come out as urine sooner than a weaker solution, and why in a greater amount?

It has generally been held that this is because the salt "stimulates" the kidney cells in some mysterious way. Aside from the fact that this means nothing, the explanation is really simpler. The salt decreases the capacity of the body colloids (*the protein colloids*) *for holding water, and this the more, the higher the concentration of the salt.* The higher the concentration of the salt in our solution, the higher must this therefore be in the blood, and secondarily (after diffusion) in all the tissues of the body. In injecting a strong salt solution we therefore not only supply free water as before, but by increasing the salt concentration in the blood and tissues, we make the colloids here give up water. This "free" water is then added to that already "free" in our injection mixture, and so the urinary output is increased *pari passu* with every increase in the concentration of the salt in the injected fluid.

A running account and further references to the literature may be found in his Oedema and Nephritis, Ed. 2, New York, John Wiley and Sons, 1915.

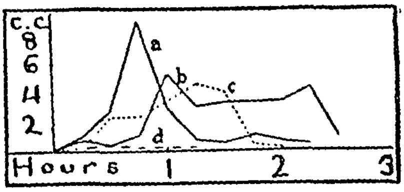

Chart 2.—Urinary output in rabbits when 125 c.c. of water are injected *in form of blood serum.*

2. We can at once test the soundness of our reasoning by substituting for the plain salt solutions one in which the solvent (water) is not free, but combined with a colloid.

The natural fluid that has these characteristics is of course, if our reasoning is correct, the blood, and so we should expect that the injection of no amount of blood would yield any increase in urinary output. That it does not is a familiar fact in physiology since the experiments of E. Ponfick[3] and R. Magnus,[4] only the interpretation of this observation has been lacking.

Chart 2 shows how the injection of a solution in which the water is combined with a colloid does not yield any increase in urinary secretion (it remains in the blood vessels). In these experiments we did not use whole blood, but sterile blood serum. In spite of the fact that the same amount is injected as in the experiments with salt solution, the curves showing the urinary output are identical with those which are obtained from normal animals which have simply been comfortably tied into an animal holder.

3. It might now be argued that blood has something specific about it that makes it remain in the blood vessels, and that it does this not simply because the water in it is held in combination with the blood colloids. This criticism is met in Chart 3, which shows the results of experiments in which water is again injected intravenously, only this time in combination with a colloid foreign to the blood, namely, gelatin. As the two curves show, a 1.5 to 2.5 per cent. gelatin solution, when injected intravenously, remains in the blood vessels and does not yield any increased urinary output.

4. If the foregoing experimental facts are correctly interpreted, it is of course to be expected that we can at will make an animal retain water in its blood vessels or give this up, depending on whether the water so introduced is given in combination with a colloid or "free." This may be proved in one and the same animal. The results of injecting water in combination with a colloid as blood serum or a gelatin solution, and "free" water as in a salt solution, are shown in Charts 4 and 5. While no increase in urinary output is observable in the first period of these experiments in which blood serum or gelatin is injected intravenously, the urinary secretion rises as soon as a salt solution is substituted for the serum. The curves are clearly the syntheses of the results obtained before in separate animals when we injected colloidal solutions or salt solutions alone.

III. CRITICAL REMARKS

To those who are disinclined to accept the teaching that the living animal represents simply a series of colloidal phases that are saturated with water, and that secretion becomes possible (in the main) only as some of this water is freed (as by increasing the salt concentration in the protoplasm of the animals), or "free" water is injected from without, these experiments, in which we take a secretion of urine or its absence as evidence that an injected fluid has remained in the blood vessels or not, may not be entirely convincing. We must meet their objections.

Mere examination of the animals while they are being injected with a colloidal solution or with a salt solution indicates that the fluid remains in the blood vessels in the former case and escapes from these in the latter. Inspection of the more superficial blood vessels (veins and arteries of the skin and ears, the carotids and the femorals) shows that, when a colloidal solution is injected, these become progressively fuller and remain so; as the vessels become more and more filled, the amplitude of the pulse waves becomes smaller and this effect persists. Even when we inject such a non-poisonous fluid as blood serum we can only inject a limited volume before we notice that the respiration of the animal is becoming embarrassed, and if we persist, the animal dies from mere overfilling of the blood vessels, and the mechanical hindrance that this offers to the maintenance of a circulation of the blood.

Intravenous injection of a salt solution is not followed by such consequences. Here the filling of the blood vessels is not so apparent, and the effect is not lasting. The respiration does not become embarrassed, and if we have previously overfilled the blood vessels with a colloidal solution and so induced a dyspnea, this is likely to improve if a strong salt solution is injected.

Further, if we have produced a (presumably) fatal hemorrhage and then saved our animal by the injection of blood serum, we can kill it subsequently by giving strong salt solutions which again decrease the volume of blood in the blood vessels.

That only the colloidal solution remains in the blood vessels is further brought home to us when we examine the injected animal at necropsy. In an animal that has been injected with a salt solution, especially if it has been a strong salt solution, the heart is normally distended with blood, or may appear underfilled, as do all the larger blood vessels. If the organs (liver, kidney, etc.) are cut across, they bleed a little or may be quite dry. If, on the other hand, a colloidal solution has been injected, the heart and large vessels are distended with blood, and when one of the parenchymatous organs is cut across, the blood fairly wells out of it.

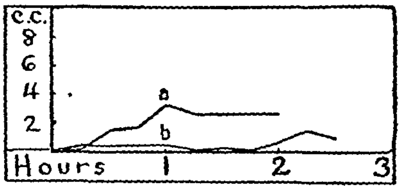

Chart 3.—Urinary output in rabbits when 125 c.c. of water are *injected in colloidal combination with gelatin.*

We know that the colloidal solution remains in the blood vessels from yet other facts. It simply cannot get out. Its loss from the blood vessels is entirely analogous to the absorption of such fluids from any of the serous cavities or the gastro-intestinal tract.

[4] Magnus, R.: Arch. f. exper. Path. u. Pharmakol., 1901, xlv, 210.

Water injected into the peritoneal cavity in combination with a colloid (blood, lymph, ascitic fluid, gelatin solution, agar-agar, native egg white, etc.) cannot be absorbed until it has been separated from the colloid, or the colloid has been removed (digested). The same is true for the absorption of the water out of these solutions when introduced into any other serous cavity or into the lumen of the intestine.[5]

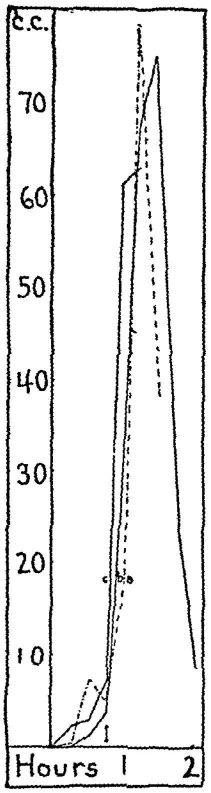

Chart 4.—Urinary secretion when salt solution follows injection of blood serum.

Finally—what will seem most convincing to many physiologists and clinicians—direct blood pressure measurements show that salt solutions do not remain in the blood, while water in combination with a hydrophilic colloid does. As is known to everyone, the rise in blood pressure which follows the intravenous injection of a 0.9 per cent. sodium chlorid solution into a normal rabbit is only temporary. In a few minutes to half an hour, the pressure has dropped back to normal. Accompanying it we have an increased urinary output. But if the same amount, say the equivalent of the calculated volume of blood in the animal, is injected in the form of blood serum or gelatin solution, the rise in arterial blood pressure (amounting to from 10 to 25 mm. of mercury) remains for hours; and in this case no increase in urinary output is noted. Especially marked are these findings if we first induce a state of low blood pressure in our animals by hemorrhage. While salt solutions give a temporary rise in blood pressure (and improvement in the general symptoms consequent on the hemorrhage), we obtain a permanent rise only if we inject a (hydrophilic) colloidal solution.

IV. PRINCIPLES OF PERFUSION IN HUMAN CASES

The foregoing experiments were made in order to formulate more clearly the principles that must guide us in combating the various pathologic conditions encountered clinically which are characterized by an abnormally low blood pressure of such grade that it in itself threatens life.

Such a low blood pressure may result from any one or any combination of the following causes: (1) a decrease in the force or the number of the heart beats; (2) a diminution in the volume of the circulating blood; (3) an increase in the capacity of the blood vessels to hold blood. Or to illustrate this in ordinary clinical terms, a low blood pressure may result from a weakened heart muscle (myocarditis); from a hemorrhage, or a loss of the watery constituents of the circulating blood (oligemia); from a vasodilatation due either to a loss of tone in the blood vessel walls themselves or to impairment of the *nervous* (so-called vasomotor exhaustion) or chemical mechanisms (loss of the active principle of the suprarenal bodies from the blood) which are in part or wholly responsible for the maintenance of this tone.

In this paper I shall disregard the question of failure of the heart itself as responsible for a pathologically low blood pressure, and discuss merely the principles involved in our ordinary therapeutic attempts at restoring a low blood pressure to normal *by introducing fluids intravenously.*

It is clear from what was said above that only a proper colloidal solution can be injected intravenously with the hope that it will remain in the blood vessels and so maintain any rise in blood pressure gained by such means over any considerable period of time. But what colloidal solution may we or is it best to inject?

After what has been said it must be self evident that the best transfusion fluid is whole blood. But the obvious difficulties and dangers attendant on the carrying out of a man-to-man blood transfusion limits its usefulness. The liquid of next choice for perfusion is that which most nearly approaches blood, namely, blood serum. Human blood serum is, however, difficult to obtain. All the possibilities of obtaining a human colloidal solution that will stay in the blood vessels resides in the use of hydrocele fluid and of the ascitic accumulations from patients with heart disease. Such fluids can be drawn when opportunity offers into sterile containers and the serum separated from the fibrin clot by the methods employed in collecting horse serum. The use of the serum from human milk is also to be counted in here. Certain dangers are, of course, attendant on the use of any of this human material, but on these not too much emphasis is to be laid, for perfusion is not at present employed for patients who are not desperately ill.

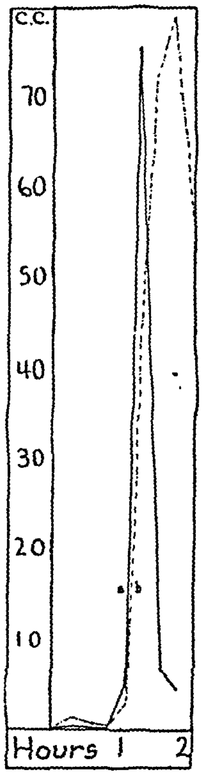

Chart 5.—Urinary secretion when salt solution follows injection of gelatin.

It was to meet these various objections that a colloidal solution suitable for intravenous injection in clinical cases and obtainable from other than human sources was sought. The materials available for such use are limited, but as our previous experiments on animals and the clinical abstracts given below would tend to show, properly prepared gelatin solutions may be used intravenously without danger.

Preparation of Gelatin Solution for Intravenous Use

Twenty-five gm. of the purest gelatin,[6] 1.5 gm. of sodium chlorid and 100 c.c. of distilled water are placed in a flask and boiled for fifteen minutes. The resulting solution is filtered through heavy paper in a hot funnel and then autoclaved for an hour at 124 C. (255.2 F.). It is then chilled in an ice-box. The gelatin has the proper colloidal qualifications if under these circumstances it solidifies. In this form the gelatin is kept until needed. In order to prepare the transfusion mixture, the flask of gelatin is warmed until it melts, when it is added to 1,000 c.c. 0.9 per cent. sodium chlorid to which have been added 2 gm. of sodium carbonate crystals ($Na_2 CO_3$ 10 H_2O) all warmed to body temperature.

---

[5] Fischer, Martin H.: Kolloidchemische Beihefte, 1911, ii, 304; Lancet-Clinic, June 22 and 29, 1912.

[6] The gelatin must be fresh and of high quality. Ordinary and old gelatin not only does not gel properly, but is often so rich in protein decomposition products as to be dangerous for intravenous use. I have found the Non Plus Ultra brand of the Deutsche Gelatine Fabriken, and the "Highest Quality" of the Heidelberger Gelatine Fabrik (Stoess & Co., Heidelberg) to do very well.

The instructions as here given must be carefully followed, otherwise trouble will be encountered from the fact that, as ordinarily done, the heating necessary to sterilize properly the gelatin decomposes it and so destroys the very properties for which it is used. When heated in the presence of a sufficient concentration of salt, this decomposition is practically avoided.

The results that have been obtained by the use of such gelatin solutions intravenously are best illustrated by a few clinical histories. I am indebted to a number of my colleagues for permission to see their patients, and wish here to express my acknowledgments. Most of all I am indebted to Dr. B. F. Alden, who was the first to try the gelatin solutions intravenously in a series of injury cases in which death seemed the only prospect.

Case 1. (Dr. B. F. Alden, San Francisco).—A. F., aged 39, Italian laborer, had always been in good health. March 3, 1913, he entered the French Hospital, the victim of a severe accident which had occurred the day before. A tree limb had fallen across his leg from a great height, crushing the upper end of the right tibia, and the head and lower third of the shaft of the femur. All structures beneath the skin, with the exception of the semitendinosus tendon had been completely severed. There existed also a compound comminuted fracture of the right tibia, fibula and ankle bones, which, however, did not bleed as all vascular communication had been severed above. The left tibia and fibula were fractured. Hemorrhage had been excessive, as practically no attempt had been made to control it. The man had been brought from the country and did not get into the hospital until twenty-four hours after the injury. The patient was in a state of profound shock. He was almost exsanguinated and showed a small, rapid, soft radial pulse, with cold extremities, excessive thirst, and shallow and rapid respiration. Blood was oozing from the lacerated wound about the knee. Strychnin, normal salt solution subcutaneously, gelatin subcutaneously, and the usual hemostatic measures were all used without improving the general state of the patient. Under ½ grain tropacocain anesthesia, administered intraspinally, the integument—which, with a single tendon alone united the crushed leg to the patient—was severed. The clotted blood and crushed bone were removed, and the large vessels in the stump were rapidly ligated; the wound was dressed and the patient rushed to bed, where his head was placed low and surface heat was applied. The pulse could now no longer be obtained at the wrist and, as death seemed imminent, it was felt that an intravenous injection of a gelatin solution was justified. Five hundred c.c. were given. As there was no radial pulse at the beginning of the injection, an accurate blood pressure reading could not be made. The needle of a Tycos instrument oscillated at 90 mm. While the injection was being made, the radial pulse gradually returned, and an hour later the blood pressure measured 125 mm. During the same time the pulse rate dropped from 130 to 88. The pressure was maintained, rising slightly from day to day, until on the tenth day after the infusion it measured 145, while at the same time the pulse gradually dropped to 78. The pressure now gradually declined to 125 mm. and the pulse to 72. The patient made an uneventful recovery.

Case 2. (Dr. D. N. Richards, San Francisco).—Mrs. E. S. R. entered St. Francis Hospital, July 2, 1913, at 5:30 p. m., at full term and in labor. Regular pains continued until 4:15 a. m., when ether was given and she was delivered of a female child. The placenta was expelled at 5:10. This was followed by profuse bleeding, which continued until the patient was practically exsanguinated. At 6 a. m. the radial pulse could scarcely be felt. The pulse was 140, the blood pressure (verified by Drs. Richards and Fraser) 58. As the patient's condition was considered alarming, an intravenous injection of 750 c.c. of gelatin solution was given. The blood pressure rose to 118 mm. within an hour, the pulse fell to 100, and the patient's general condition improved greatly. For the following four days the pressure varied between 105 and 110 mm., the pulse between 85 and 100. The patient made a good recovery, leaving the hospital July 17.

Case 3. (Dr. B. F. Alden, San Francisco).—J. P. G., aged 46, Frenchman, was operated on by an associate, Feb. 7, 1913, for a ruptured appendix. A suppurative peritonitis with two fecal fistulas, one into the cecum, the other into a loop of the ileum, resulted. April 15, the openings in the intestine were repaired with Connell's interrupted sutures of silk covered by continuous Lembert catgut sutures. No excessive bleeding was noticed at the time of the operation, but one of the Connell sutures must have lacerated a large vessel, from which an active hemorrhage into the lumen of the intestine resulted. April 16, a lowered blood pressure with symptoms indicative of hemorrhage were observed. The outer wound was opened and the intestinal site explored, but as no serious bleeding was found, the intestine was not disturbed. The wound was repacked with gauze. On the morning of April 18, a large bowel movement of coagulated blood was observed. In the meantime the patient had declined steadily. Ten c.c. of horse serum were injected subcutaneously. A second blood stool containing a large amount of fresher blood occurred, when another 10 c.c. of horse serum and 300 c.c. of physiologic salt solution were given. The patient continued to decline, exhibiting all the alarming symptoms of active hemorrhage. At 3:30 p. m., April 18, the patient was reported dying. He was pulseless at the wrist. Oscillations in a Tycos instrument were observed at 80 mm. An immediate intravenous injection of 500 c.c. of gelatin solution was ordered. Half an hour later the patient's pulse had dropped from 156 beats to 138 and had gained in volume, strength and regularity. The blood pressure rose to 110 mm., and by the following morning it was 140 mm. This pressure persisted, while the pulse rate within three days gradually fell to 74. An uninterrupted convalescence followed, and at the present time this patient is well.

Case 4. (Drs. W. B. Coffey and C. A. Walker, San Francisco).— Mr. B. entered St. Francis Hospital, July 26, 1913, having been ill for four days. The patient showed marked evidences of general intoxication. Examination revealed tenderness in the region of the appendix. An immediate operation was performed which revealed a ruptured appendix with marked circumscribed peritonitis. The patient showed marked shock following the operation. A 0.9 per cent. sodium chlorid solution was dripped into the rectum throughout the day following the operation. The patient did not rally. The pulse became progressively weaker and rose to 130, while the blood pressure fell until at 9:30 p. m. it measured 86 mm. As death seemed the only outcome, gelatin solution was given intravenously. This was started at 9:50, the blood pressure at this time measuring 85 mm., the pulse 128. The following records show the rise in blood pressure during the injection:

After 150 c.c. it was 96.
After 250 c.c. it was 110.
After 400 c.c. it was 128.
After 500 c.c. it was 132.

As this pressure was deemed sufficiently high, the injection was stopped. The patient's general condition improved at once, the radial pulse filling out and the rate dropping to 90. The following morning the blood pressure was 119, the pulse 90. That afternoon the pressure rose to 128, while the pulse dropped to 85. The pressure remained, while the pulse gradually returned to normal. The patient made an uninterrupted recovery.

Case 5. (Dr. B. F. Alden, San Francisco).—M. C., aged 36, a native of France, because of an empyema of the left thorax following a lobar pneumonia, was transferred to the surgical service from the medical side, May 20, 1913, for a thoracotomy. Before he was brought to the operating room the patient showed the weak, thready pulse, rapid respiration, extreme pallor, drawn face, and cold and clammy extremities, ears and neck of profound shock. When placed on the operating table, the patient seemed *in extremis,* and was practically pulseless. Because of this, no proper blood pressure reading could be made. The anesthetist advised against the use of an anesthetic. As it was agreed that the patient would die, 500 c.c. of the gelatin solution were injected into the median basilic vein. The incision was made without anesthetic, as the patient was unconscious. Within ten minutes after the beginning of the perfusion, a perceptible radial pulse was noted, and this gradually improved in quality. A section of the eighth rib was now removed, and drainage of the pleural cavity effected. The patient recovered consciousness while on the operating table, and the blood pressure rose to 118 mm. It continued to mount until it reached 154 the following day. At the same time the pulse rate fell from 135 to 106. Two days later the pressure sank to 106, while the pulse mounted to 136. As the drainage was found to be inefficient, by reason of adhesions in the pleura, the patient was reoperated on under nitrous oxid and oxygen anesthesia. This was done without difficulty. The pressure then again rose to 126 mm. and remained there, while the pulse fell back to 100. At the present writing this patient has so far recovered as to be up and about.

Case 6. (Dr. B. F. Alden, San Francisco).—M. B., aged 54, a Frenchman, for some time preceding his operation had been unable to take food owing to an almost complete stenosis of the pylorus secondary to a carcinoma. He refused operation until May 13, 1913, when his condition had grown so grave from starvation that operative interference hardly seemed advisable. The blood pressure was less than 95 mm. As a prophylactic measure he was given 500 c.c. of the gelatin solution intravenously. The pressure rose rapidly to 115 mm., and it was decided to attempt an exploratory incision. An inoperable pyloric carcinoma being found, a posterior gastrojejunostomy was performed. Throughout the operation and afterward the patient's pulse and pressure continued good. After the operation he improved rapidly, vomiting but once several days after. In the afternoon after his operation the blood pressure was 120, on the next day 136 and for four days more 150 to 160, after which it fell gradually to 128, where it remained. The pulse rate fell in this same period from 95 to 86, and then more gradually to 76. At present he is walking about in better health than for months past. This improvement is due, of course, to his ability to take food, but the surgeons concerned felt that the necessary operation was made possible only because the patient was first perfused with gelatin.

It can, of course, be foreseen that what may actually be accomplished through gelatin transfusion in any case of low blood pressure depends on the intensity, persistence and nature of the factors responsible for it. Viewed in this light, it is not remarkable that our experience thus far has seemed to indicate that cases of shock consequent on simple hemorrhage are most easily relievable. Even those of our patients who showed extreme degrees of anemia rallied. Shock consequent on injury or a surgical operation in the ordinary "clean" case seems to be controllable almost as easily. Least hopeful are the septic cases in which the low blood pressure is in large measure dependent on a heart suffering from the general intoxication. This is illustrated in Case 7.

Case 7. (Drs. W. B. Coffey and C. A. Walker, San Francisco). Mr. C., aged 32, a laborer, was brought into St. Francis Hospital at 1 p. m., July 25, 1913, with the diagnosis of a ruptured typhoid ulcer. He had had typhoid since July 1. It was felt that the patient could not live through an operation. The blood pressure was 65 mm., and as it was felt that the patient would certainly die, an intravenous infusion of gelatin solution was started at 2 p. m. After 300 c.c. had been injected, the pressure rose to 90 mm., after 400 c.c. to 96 mm., and after 500 to 99 mm. At this point the abdomen was opened under local anesthesia and found filled with fluid, fecal in character. The opening in the small intestine was quickly located and closed. The gelatin perfusion was continued during the operation, the blood pressure rising steadily even during operation as follows: after 600 c.c. had been injected it was 106 mm., after 700 it was 108 mm., after 850 it was 108 mm. This higher pressure continued until 6:10 p. m., when he showed signs of a rapidly falling pressure and then died.

Besides this patient, I have seen two others with toxemic shock who died. One was a woman suffering from a hemolytic streptococcus infection of the blood stream after a miscarriage; the other, an ileus in the course of a peritonitis secondary to a ruptured appendix. In the former we raised the blood pressure from 75 mm. to 118 mm., where it remained for two days, when the patient died. In the second the pressure was raised from 58 mm. to 124 mm. This patient also died.

As this paper deals only with the use of colloidal perfusion mixtures, I purpose discussing in a subsequent paper some additional methods at present available in the treatment of toxemic shock.

350 Post Street.

THE INFLUENCE OF CHANGES IN THE CHEMICAL ENVIRONMENT ON THE LIFE AND GROWTH OF TISSUES *

LEO LOEB, M.D.
St. Louis

In addition to the method which, with a view of analyzing the effect of experimental variations in the physical and chemical environment on the life and growth of tissues, I published in 1897, and which permits study of the life and growth of tissues in the test-tube, outside the body,[1] and with a later modification also inside the body — the latter serving as a living thermostat[2] — there exists another method of studying the influence of apparently slight chemical changes on life and growth of tissues, namely, that of comparing the growth of tissues after transplantation into the same individual in which it originated (autotransplantation) and after transplantation into another individual of the same species (homoiotransplantation) and after transplantation into other species (heterotransplantation). In 1902[3] and again in 1907[4] I showed that tumors which die after homoiotransplantation live usually after autotransplantation. It may happen that occasionally in such a tumor a small peripheral part may remain alive even after homoiotransplantation, but in the same tumor after autotransplantation the whole tumor remains alive. I drew on the basis of these experiments at that time the conclusion that the chemical constitution of body fluids differs in in different individuals of the same species. It was of interest to make a systematic study of the influence of these chemical differences on the life and growth of normal tissues. While a few observations recorded in the literature suggested that autotransplantation of tissues is sometimes more successful than homoiotransplantation, this problem had hitherto mainly been considered from the practical point of view of the surgeon without regard to its great theoretical significance as a study of the effect of a difference of chemical environment on tissue life and growth.

Without going into a detailed statement of our results, I wish here to report briefly some of our general conclusions which are based on our work and that of our collaborators, on the surface and subcutaneous transplantation of various kinds of skin, and on the subcutaneous transplantation of kidney, thyroid, uterus and testicle. While part of this work has been reported within the last six years, other publications will follow in the near future.

1. In the case of the majority of tumors and normal organs, some of the transplanted tissue remains alive and may grow after autotransplantation, while after homoiotransplantation it perishes. In the case of certain tumors, and perhaps in rare instances in the case of normal tissues, however, even after homoiotransplantation, transplanted cells may remain alive and in some cases grow.

2. In some of those tissues which after homoiotransplantation remain for some time alive, metabolic changes which represent a deviation from the normal can be shown to take place, and it may be assumed that those changes usually occur, even in cases in which at present we cannot demonstrate their existence. Thus, after surface homoiotransplantation of pigmented skin, an interference with the normal process of pigmentation can be observed,[5] after homoiotransplantation of thyroid the production of colloid is deficient.[6]

3. Different tissues show a somewhat different degree of resistance after homoiotransplantation (and also after autotransplantation). Gland tissue of the uterus, for instance, shows more resistance after homoiotransplantation than kidney tissue, and probably also more than unstriated muscle of the uterus. There exist also within certain limits differences in individual experiments, depending perhaps on a better mutual adaptation of the organs of one individual to the body fluids of another individual of the same species.

4. *After a first period*, usually lasting somewhat less than one week, in which no marked difference exists in the behavior of the autotransplanted and homoiotransplanted pieces, a gradual destruction of the latter sets in. In some cases, metabolic tissue changes taking place after homoiotransplantation may perhaps be of a sufficiently serious character to lead to a direct destruction of the transplanted pieces or prevent their recuperation from the injurious conditions caused by the process of transplantation. This may be sometimes so, perhaps, in the case of unstriated muscle of the uterus, or after homoiotransplantation of certain tumors. Furthermore, after transplantation into other species, the toxicity of the body fluids may injure the transplanted tissue to such an extent that death results. (In vitro the blood plasma of a different species seems to be relatively innocuous. We have, however, to consider that here, even if a toxic substance should be present in the body fluid, the quantity of it coming in contact with the transplanted tissue would be extremely small, while in the living body the blood stream would constantly carry new toxic substance to the transplanted tissue. We know that minute quantities of a toxic substance may exert a stimulating effect, where somewhat larger quantities paralyze and destroy.)

While the directly destructive effect of body fluids needs further investigation, there can be no doubt that a typical and frequent mode of destruction of homoiotransplanted (and sometimes of autotransplanted) tissues is of a different character. While the vitality of the tissues has not been essentially impaired after homoiotransplantation, and they may even grow, and the metabolic changes they underwent in the different chemical environment did not therefore markedly interfere with their power to live or even to propagate, these metabolic changes lead to a new condition in the host tissue, which secondarily brings about a destruction of the transplanted piece, namely, these metabolic changes cause (*a*) an increased activity on the part of small mononuclear cells (probably lymphocytes) and (*b*) a destructive activity on the part of the connective tissue of the host.

5. The mononuclear cells collect around the transplanted tissue, penetrate into it and destroy its cells. While in the autotransplanted tissue the immigrating fibroblasts remain in an active young state—if one wishes to use the latter designation—in the homoiotransplanted tissue the fibroblasts very soon form dense fibrous material which separates the transplanted parenchyma into small islands, compresses them and leads thus to their destruction. There is possibly also present a greater ingrowth of fibroblasts in the case of the homoiotransplanted tissue. We may conclude, therefore, that the metabolic changes taking place in tissues *after homoiotransplantation stimulate the activity* of the lymphocytes and cause the altered function of the fibroblasts which now produce fibrous tissue in large quantity. This destructive activity of lymphocytes and connective tissue in homoiotransplanted tissue—and under certain conditions also in other cases —we observed after subcutaneous transplantation of skin;[7] after surface transplantation of skin;[8] after transplantation of kidney, where the connective tissue changes are also very marked;[9] of thyroid,[10] and of uterus.[11]

6. The activity of lymphocytes and of connective tissue is to some extent independent of each other: while in many cases the two act together, in some cases the one prevails, in other cases the other.

7. In the case of certain organs as, for instance, the kidney, also pieces transplanted into the subcutaneous tissue of the own animal are attacked by lymphocytes and connective tissue. However, in the case of the kidney, the autotransplanted are attacked and destroyed at a later period than the homoiotransplanted pieces. In this case we *must assume that under the* abnormal conditions after transplantation into the subcutaneous tissue even in the same animal, such abnormal metabolic products are formed that an attack by the host tissue and a secondary destruction takes place.

8. The substance secreted by the corpus luteum which calls forth growth in the uterine mucosa may be active not only in the autotransplanted, but even under

the adverse conditions prevailing in the homoiotransplanted tissue. But in the latter case a weakening in the effect of the growth substance takes place. The injurious action of body fluids in the other individual detracts from the efficacy of the growth substance.

9. On the basis of these observations, we may formulate the following conception of the relations between different tissues: A certain metabolic activity on the part of parenchyma of various organs determines the attitude of lymphocytes and of fibroblasts toward the parenchyma. If the activity is normal, lymphocytes do not, or only to a slight extent, enter the parenchyma. The connective tissue is held in a definite state of activity. If within certain limits (which still permit the continued life and even growth of the tissue) the metabolic condition of the parenchyma becomes abnormal, the connective tissue in contact with the parenchyma loses its normal state of activity, produces fibrous bands (and perhaps the fibroblasts invade the parenchyma in larger number) and thus compression is exerted on the parenchyma, and cirrhosis caused and ultimately the transplanted tissue is destroyed. This is one mode in the production of cirrhosis. Under other conditions, the presence of actual defects in the parenchyma may under the guidance of stereotropic stimuli[12] also produce an invasion by connective tissue and thus lead to cirrhosis. We notice in certain mucous membranes that directly beneath the epithelium the connective tissue is richer in cells than elsewhere. This may, in conformity with the theory just presented, be due to the stimulating effect of the metabolism of the epithelium similar to that exerted by normal parenchyma on the connective tissue after autotransplantation.

A similar abnormal metabolic condition of parenchyma may perhaps also be produced in certain states of immunity, and thus it may be explained that in animals immunized against tumor growth, various mononuclear leukocytes invade or surround the tumors. On the basis of our theory, this would be a process secondary to metabolic changes resulting from the effect of substances produced in the animal through immunization and acting on the tumor cells, or directly produced through immunization in these tumor cells, the combination of this immune substance and the tumor cells influencing certain host cells in a manner comparable to that caused by parenchyma after homoiotransplantation.

Connective tissue and lymphocytes may therefore be regarded as organs of attack, lying quiescent under ordinary conditions, but exerting their efforts as soon as within given limits certain pathologic changes take place. While according to the view commonly held and mainly inaugurated by Weigert (so-called inflammatory) connective tissue growth accompanying round cell infiltration is of a regenerative character, destined to fill out actual defects or to take the place of cells markedly injured and unable to continue a vigorous life, our observation points to the conclusion that also tissues not essentially injured in their vitality and not markedly changed in their morphologic character may as a result of altered metabolic conditions influence lymphocytes and connective tissue in such a manner that cirrhosis and a partial or total destruction of the parenchyma results.

REPORT OF TYPHOID EPIDEMIC OCCURRING THREE MONTHS AFTER THE USE OF PROPHYLACTIC VACCINE

E. H. TROWBRIDGE, M.D., B. A. FINKLE, M.D.
AND
ELIZABETH M. BARNARD, M.D.
First, Second and Third Assistant Physicians, Respectively, Minnesota School for Feeble Minded and Colony for Epileptics
FARIBAULT, MINN.

During the early months of the spring of 1914 several cases of typhoid fever occurred in the Minnesota School for Feeble Minded and Colony for Epileptics at Faribault. An exhaustive search through the use of the Widal test in some 1,601 inmates disclosed the presence of a positive reaction in twenty-eight. Further investigation by means of isolation tests revealed the fact that eight of these inmates were active carriers.

To prevent the development of new cases, the administration of typhoid prophylactic was begun immediately. A total of 1,520 patients were inoculated in the usual manner. All patients having given positive Widals were isolated until the completion of the prophylactic treatment. New cases ceased to develop following the administration of the prophylactic until the outbreak of the current epidemic.

In order to determine the agglutinating property of the blood, following the prophylactic treatment, specimens of blood were taken from all who were inoculated. Complete results showing reactions in males and females, and the percentage are given in detail in Table 1.

TABLE 1.—RESULTS OF WIDAL TESTS MADE FOLLOWING IMMUNIZATION

	Male		Female		Total	
	No.	Per Cent.	No.	Per Cent.	No.	Per Cent.
Positive reaction....	262	18.8+	215	15.4+	477	34.3+
Atypical reaction....	130	9.3+	135	9.7+	265	19.0+
Negative reaction...	317	22.8+	331	23.8+	648	46.6+
Total Widals taken	709	51+	681	48+	1390	100

About the middle of September, three months subsequent to the completion of the administration of the antityphoid vaccine, several patients were admitted to the hospital with symptoms somewhat resembling those of typhoid fever. As these patients had been previously inoculated, a diagnosis of typhoid fever was not justifiable without a more thorough investigation.

On request the State Board of Health kindly consented to assist us in this task. Blood cultures were taken from twelve of the patients with the result that the *Bacillus typhosus* was found in one instance. This same patient gave a positive Widal reaction following the use of the prophylactic, and also after the onset of the disease. At necropsy typhoid ulceration was found in the ileum, thus verifying the nature of the infection.

Specimens of feces and urine were collected and examined; the *Bacillus typhosus* was isolated in two cases and the bacillus paratyphosis in three. Widals were made at intervals during the course of the epidemic. Of the forty-six patients examined, thirty-nine gave positive Widals, one gave an atypical reaction, two gave agglutinations with the bacillus paratyphosis, and three remained negative, although manifesting clinical signs of typhoid fever. Due to oversight, no Widal was made on illustrative Case 3.

---

[12] Concerning the significance of stereotropic stimuli for the growth of tissues, compare the following paper: Loeb, Leo: Ueber die Regeneration des Epithels, Arch. f. Entwicklungsmechanik, 1898, vi, 237, Chapter 13.

Owing to the complexity of symptoms, including pharyngitis, cultures from the nose and throat were made, which showed the presence of diphtheria bacilli in eleven of the patients. These being of a non-virulent type, prove conclusively that they bore no important relation to the course of the disease.

The typhoid occurring in separate buildings scattered over a wide area made it possible to dismiss the previous carriers as a source of infection, and to focus attention on the food, milk and water supply.

The distribution of food is from a central kitchen, and the milk supply is from the institution dairy. The major portion of the water is obtained from the city water supply, and the remainder from our own artesian well. The general water supply as a source of infection was ruled out, since sewage contamination was found to be improbable.

A spring on the east side of the grounds was considered, since it is possible for it to receive surface drainage, and several of the patients had had access to this water. As the majority of the patients had not partaken of this water, it was evidently not the primary source of infection. No carriers were found among those concerned with the preparation and distribution of food.

Investigation of the conditions existing at the dairy disclosed the fact that the dairyman had an ambulatory case of typhoid. The dairyman's wife was ill at the time; her symptoms were of an indefinite nature and a subsequent Widal was found to be positive. Neither the dairyman nor his wife had previously received prophylactic treatment. A milker, one of the inmates, had been removed to the hospital a few days previous to the investigation of the dairy, and after a prolonged prodromal stage developed clinical typhoid fever. He had returned recently from a short vacation in an adjacent town, where he no doubt contracted the disease. The daily association of the dairyman and his wife with this milker indicates that he was the original source of infection. Precautionary measures were immediately instituted. The dairyman and his wife were relieved from duty, and all the milk was sterilized during the next four weeks. Milk formed part of the diet of every individual who contracted the disease.

After the incubation period of twenty-one days had passed, new cases ceased to develop, showing conclusively that the milk supply was the source of the epidemic.

A total of fifty-seven cases in this epidemic were diagnosed as clinical typhoid. Of this number forty-six were inmates and the remainder were employees. Only one of the employees had received the prophylactic, and three of the inmates were uninoculated.

The following typical case histories are presented to illustrate the symptoms as they appeared in the clinical picture.

REPORT OF CASES

Case 1.—(No. 7) G. M., girl, aged 18; admitted to the hospital Sept. 23, 1914; discharged Dec. 23, 1914.

Personal History.—Widal test made May 20, 1914, negative; typhoid prophylactic administered May 27, June 6 and 16, 1914. Widal test made July 9, 1914, negative.

Present Illness.—Began with severe headache, anorexia, nausea and vomiting and diarrhea, followed by marked prostration, restlessness and delirium. Tongue coated, sordes marked, abdomen very tender, spleen palpable. Rose spots appeared on the abdomen. Temperature on admission, 101 F., and 104 to 105 in the afternoon for ten days, gradually declining to normal on the thirty-sixth day. Stools contained occult blood on the eighth day, and two fairly large intestinal hemorrhages occurred on the thirteenth day.

On the fourteenth day 3,000 units of diphtheria antitoxin were administered.

Laboratory Findings.—Widal test made Sept. 29, 1914, atypical. Widals made Oct. 3, 1914, and Nov. 1, 1914, positive. Blood culture taken Sept. 30, 1914, negative. Throat culture taken Oct. 10, 1914, showed diphtheria bacilli of a non-virulent type.

Case 2.—(No. 9) A. E., man, aged 23. Admitted to hospital Sept. 24, 1914. Discharged Nov. 25, 1914.

Personal History.—Widal made May 6, 1914, negative. Typhoid prophylactic administered May 27, June 8 and 22, 1914. Widal made July 1, 1914, positive.

Present Illness.—Complained of headache, sore throat and abdominal distress for about a week before admission to hospital. On admittance had headache, pain in limbs, coated tongue, some abdominal tenderness and anorexia. Constipated during entire course of the disease. Temperature 103.4 F. when received at hospital, and fluctuated between 102 and 104 for eight days. Began to decline the ninth day, reaching normal on the twenty-first day. From twenty-first to thirty-first day the temperature was very irregular, varying from 96.4 to 101.8. It remained subnormal or normal on the forty-seventh and forty-eighth days, and rose to 101 on the forty-ninth day, dropping to normal on the following day. On the seventeenth day of the disease 3,000 units of diphtheria antitoxin were given.

Laboratory Findings.—Widals made Sept. 28, 1914, Nov. 1, 7, 9, 13 and 17, 1914, negative. Widal made Nov. 22, 1914, positive. Blood culture taken Sept. 30, 1914, negative. Throat culture taken Oct. 10, 1914, showed diphtheria bacilli of a non-virulent type.

Case 3.—(No. 10) M. L., man, aged 24, admitted to hospital Sept. 24, 1914. Died Oct. 16, 1914.

Personal History.—Widal made May 30, 1914, negative. Typhoid prophylactic administered June 5, 15 and 25, 1914. Widal made Aug. 17, 1914, negative.

Present Illness.—For a few days before entering hospital the patient was annoyed by frequent epistaxis, diarrhea was marked and pains in the back were severe. Temperature 101.6 F. on admission to hospital, and rose to 104.6 the following day. Temperature remained high until the fifteenth day in the hospital, when there was a sudden drop of 99, with evidence of perforation. The next day his temperature rose to 105, the abdomen became tense and the patient died.

Laboratory Findings.—Blood culture taken Sept. 30, 1914, negative. Necropsy showed two small perforations in the ileum and numerous ulcers, some beginning, some mature and others healing.

Case 4.—(No. 13) C. S., man, aged 21. Admitted to hospital Sept. 26, 1914. Discharged Nov. 25, 1914.

Personal History.—Widal made May 30, 1914, negative. Typhoid prophylactic administered June 5, 15 and 25, 1914. Widal made July 14, 1914, negative. Widal made July 18, 1914, positive.

Present Illness.—Five days prior to entering hospital there was anorexia, fatigue and pains in the back and neck. Entered hospital September 26 with tongue heavily coated, stools watery and very offensive. Temperature 101 to 103.6 for thirty-three days, when it began to recede and the patient made an uneventful recovery.

Laboratory Findings.—Blood count normal. Blood culture taken Sept. 30, 1914, negative. Widals made Oct. 26 and Nov. 1, 1914, positive. Throat culture taken Oct. 10, 1914, showed diphtheria bacilli of a non-virulent type.

Case 5.—(No. 20) H. T., girl, aged 5, admitted to hospital Sept. 29, 1914. Died Nov. 27, 1914.

Personal History.—Typhoid prophylactic not given.

Present Illness.—Admitted to hospital with bronchitis. Temperature 102 and 98 to 99 for twenty-four days, then rose suddenly to 103 with extreme prostration, restlessness and delirium. Sordes marked, abdomen tympanitic, spleen palpable. Temperature ranged from 103 to 105 in the afternoon, until death occurred on the fifty-eighth day.

Laboratory Findings.—Widals made Oct. 12, 1914, and Nov. 1, 1914, negative. Widals made Nov. 7, and Nov. 9, 1914, atypical. Widal made Nov. 13, 1914, positive. Necropsy: Ulcers found in large number in the ileum.

Case 6.—(No. 31) C. C., woman, aged 36, admitted to hospital Oct. 5, 1914. Discharged Nov. 25, 1914.

Personal History.—Widal made May 21, 1914, negative. Typhoid prophylactic administered June 2, 12 and 22, 1914. Widal made July 11, 1914, negative.

Present Illness.—Patient suffered from anorexia and general malaise for ten days. Then had a sudden, severe rigor with throbbing headache, severe backache and pain in the chest. Was constipated and had a racking cough. There was a marked tenderness in the right iliac region, tongue coated, sordes marked, rose spots on abdomen. Crepitant râles could be heard in the bases of both lungs posteriorly, but no dulness was found. Temperature on admission 100.6 and ranged from 103 to 104 in the afternoon for nine days, then gradually declined and reached normal on the sixteenth day.

Laboratory Findings.—Widal made Oct. 26, 1914, atypical. Widals made October 29 and November 1, 7, 15, 17 and 22, negative. On November 17 agglutination was obtained with the *Bacillus paratyphosus,* and this bacillus was isolated from the stool.

Case 7.—(No. 43) C. M., man, aged 17, admitted to hospital Oct. 22, 1914. Discharged Dec. 4, 1914.

Personal History.—Widal made May 6, 1914, negative. Typhoid prophylactic administered April 30, May 11 and 21, 1914. Widal made Aug. 13, 1914, negative.

Present Illness.—Complained of headache and abdominal pain two days previous to admission. On admission the patient was very nervous and covered with profuse perspiration; tongue heavily coated, anorexia, slight abdominal tenderness over splenic area. Spleen became palpable and a few rose spots appeared. Constipated during course of disease.

Laboratory Findings.—Widals made Nov. 1 and Nov. 24, 1914, positive.

The foregoing histories illustrate a more typical course of typhoid than is presented in the majority of the cases. Symptoms common to all cases were anorexia, indefinite pain in back, neck or abdomen, headache and constipation. Acute toxemia and marked prostration were present in but three of the previously inoculated patients. In fact it is worthy of note that many of the classical symptoms of typhoid, such as enlargement of the spleen, rose spots, epistaxis and abdominal tenderness were absent in most cases. However, the course of the disease did not appear to be appreciably shortened. The mortality among the vaccinated was 9.1 per cent., or less than one-half of that occurring among the unvaccinated, which was 23 per cent.

The cause of an epidemic of this nature so shortly after the completion of vaccination with the antityphoid vaccine is a subject for further discussion.

Various reports submitted by recent investigators who have had vast experience in the use of the prophylactic among large numbers of individuals, show that it is not an uncommon occurrence for typhoid fever to develop among a certain proportion of protected persons.

The use of the vaccine by the Germans in 1904 in the Herero campaign in Southern West Africa, resulted in a diminution of the occurrence of cases among the protected to about one-half as compared with that among the unprotected. The mortality among the unprotected was about four times as great as among the protected.

Figures computed by Col. R. H. Firth, covering the first six months of the year 1911, relative to vaccinated soldiers in India, show that the case incidence for typhoid was approximately five times greater among the non-protected than among the protected.

In a recent article by Frederick F. Russel,[1] U. S. A., are cited the remarkable results obtained by the use of the prophylactic in the United States army during the past six years. He says:

> Table 1 shows that the number of cases in the United States proper has fallen from 3.53 per thousand men to 0.03 in the six years; the death rate has fallen from 0.28 in 1909 to zero in 1913. In both instances the greatest improvement has been during the past three years since the vaccination was made compulsory.

No doubt these extraordinary results were in part due to the fact that camp sanitation was greatly improved and the chance of infection reduced to a minimum.

In the epidemic under consideration about one-half as many cases occurred in the protected as in the non-protected, and the mortality among the protected was less than one-half that among the non-protected.

No doubt the proportion of cases among the protected individuals would have been greatly reduced were it not for the fact that the milk, which was the source of infection, was saturated from day to day with typhoid bacilli.

So far as we are able to ascertain from the literature investigated, there is no record of a protected community having had one of the chief sources of food supply contaminated with typhoid bacilli over an extensive period of time, as occurred in this recent epidemic.

Other factors to be considered which might influence the proportion of disease incidence in vaccinated individuals, are as follows:

The possibility of the vaccine used having been overheated during its preparation, which accounted for the unsatisfactory results obtained by those who first experimented with its use. The use of vaccine which has deteriorated from not being kept at the proper temperature, or on which the time limit has expired. Faulty technic in the method of administration. Failure to adhere to the proper time interval between inoculations and to the correct number of bacteria injected.

The vaccine used in inoculating individuals connected with this institution was prepared and furnished entirely by the State Board of Health, used within the specified time limit, and kept at the proper temperature. The method of administration, the dosage, and the time interval were adhered to as recommended by the State Board of Health, except that 10 minims instead of 7½ were given at the first inoculation. Statistics show that 65 to 70 per cent. of exposed individuals have a natural immunity and therefore do not contract the disease.

It is evident from a study of this epidemic, and from the experience of others, that the typhoid vaccine in some cases fails to confer immunity, or confers only partial immunity.

Laboratory investigations by means of the Widal reaction have shown in those cases previously inoculated with the vaccine, that the blood in most cases has acquired the power of agglutinating typhoid bacilli.

---

[1] Russel, F. F.: Antityphoid Vaccination in the Army During 1913, The Journal A. M. A., May 2, 1914, p. 1371.

We know that following a clinical attack of typhoid fever the agglutinating property of the blood is present, and that frequently this is lost after varying lengths of time, while the individual possesses as a rule a lifelong immunity. At present the only laboratory index by which immunity is suggested is the appearance of agglutinins in the blood. The occurrence of clinical typhoid fever in those having been previously inoculated proves that the appearance of agglutinins in the blood is not a positive index of immunity.

Of those who developed typhoid fever in this epidemic, 14.3 per cent. gave positive Widals after inoculation, 21.4 per cent. gave atypical reactions, and 64.3 per cent. gave negative reactions.

Negative blood reactions following the use of the prophylactic may be due to one or more of the following factors: incorrect interpretation of the reaction; improper dilution of the serum; the use of freshly isolated cultures, which often resist agglutination; and, decomposition of the blood, due to incomplete drying of the specimens collected. It is also worthy of note that the agglutinating power of the blood does not remain constant, which is clearly shown in Table 2.

TABLE 2.—RESULTS OF WIDALS MADE IN 127 INDIVIDUALS (MALES) AT TEN-DAY INTERVALS FOLLOWING FIRST, SECOND AND THIRD INOCULATIONS

	Reaction Following First Inoculation		Reaction Following Second Inoculation		Reaction Following Third Inoculation	
	No.	Per Cent.	No.	Per Cent.	No.	Per Cent.
Positive reaction....	12	9.4+	67	52.7+	37	29.1+
Atypical reaction....	9	7.0+	15	11.8+	22	17.3+
Negative reaction...	106	83.5+	45	35.4+	68	53.5+
Total Widals taken.	127	100	127	100	127	100

Reviewing the findings in the preceding table, it is noted that the positive and atypical reactions begin to appear following the first inoculation. Following the second inoculation, there is a marked increase in the positive and a slight increase in the atypical reactions. The positives following the third inoculation decrease almost 50 per cent., while the atypicals show a steady increase.

CONCLUSIONS

1. Typhoid fever may be contracted by individuals who have received the prophylactic and who subsequently show a positive Widal.
2. The course of the disease is not appreciably shortened in vaccinated individuals.
3. The mortality is markedly reduced among protected persons.
4. Protected persons having typhoid fever fail to give many of the classical symptoms of the disease.
5. The development of paratyphoid is not prevented by the use of the typhoid prophylactic.
6. The degree of immunity conferred by the prophylactic in some cases fails to prevent the development of typhoid when the individual has been subject to repeated exposure.
7. The Widal reaction as a criterion of the presence of immunity is of uncertain value.

Typhoid vaccination applied as a routine measure in all of our hospitals and institutions is the one and only method to pursue to eradicate this ever present, serious, and often fatal disease. As a step in this direction State Boards of Health throughout the country are giving their cooperation and furnishing the vaccine free, to stimulate its use.

To the Minnesota State Board of Health we owe a debt of gratitude for their ever willing and hearty cooperation; their assistance in locating the source of the epidemic; and their promptness in performing the various laboratory tests.

MEDICAL INSPECTION OF OPEN AIR SCHOOLS

JOHN AIKMAN, M.D.
Attending Physician, Open Air School
ROCHESTER, N. Y.

Since the introduction, in 1908, of open air schools into the educational system of America, the number of these schools has increased at a surprising rate. To-day every city has an open air school, and the general plan is well known to all.

It is not the object of this paper to deal with the whole subject of this type of school, but with a feature which, up to this time, has received little comment.

As these institutions differ in many ways from the ordinary school, so also does the medical inspection present different problems.

The Edward Mott Moore Open Air School of this city was among the first to be opened in America, and we have been able in the past six years to try out various plans for medical inspection. After many experiments we have developed a system that is meeting requirements. As many physicians have been and will be called on to supervise work of this nature, we have thought that the results of our experiences might be of value to them in undertaking such work.

I will endeavor to outline briefly the work as it is carried on at the present time.

The medical inspection of our school is not under the direction of the city school inspectors, but is provided by the Rochester Public Health Association, which maintains a general dispensary as well. In many ways this removal from the regular school system is an advantage. The child is really taken as a patient of the association, and all problems of physical welfare are settled by physicians from the staff. Thus it is possible to make complete physical examinations, while in the regular schools they are very limited, as the child must be examined dressed. The difficulty of having directions followed in regard to corrections of physical ailments, which presents such a problem in the regular schools, is here eliminated, as we have, and exercise, the right to exclude or dismiss any children not following out our instructions. Of course such children are allowed to return to their former schools. Under these instructions would come removal of tonsils and adenoids, fitting of glasses, dental work, etc.

The routine now is as follows: All applications for admission are made at the association building, and the examinations are made on a certain afternoon of each week by the medical director of the association. If the case is suitable, recommendations are made for filling the teeth, removal of tonsils and adenoids, treatment of skin conditions and correction of anything that would prevent the child getting the most good out of the school.

At one time we simply made recommendations for these corrections and then admitted the children, but now we will not admit a case until all instructions have been carried out. This makes a reexamination necessary before the child can be put on the waiting list. Thus we are certain that the children are in good condition, and we are saved the trouble of forcing the parents to care for these matters later.

After the first examination, a visit is made at the home by the school nurse, who reports back on the home and financial conditions. If the parents are unable to take the child to a private physician for such care as is needed, the child is admitted as a patient of the association dispensary, where all examinations and operations may be secured. The nurse on this visit gives advice as to food, sleeping quarters, open windows, etc. She also fills out a report card on the home, and takes the history of the case as outlined.

Before we had a special nurse to visit these homes, the parents seemed to have an idea that the school would provide all the food required each day, and children were sent to school without breakfast, and some had no meal at night. As no school pretends to give a full diet, this made treatment, in not a few cases, very difficult. Such matters are now explained by the nurse.

If all directions have been carried out, the name is sent to the school, and when a vacancy occurs, the child is admitted.

The nurse gives the child a bath, takes a record of his weight, height, pulse, temperature and chest expansion on the day of admission. These records, together with the report of the health association examinations, the nurse's report on the home and history are before the physician when he makes his first examination at the school. Then the child is given a fairly complete physical examination, which is recorded on the chart. A test for the percentage of hemoglobin is also made.

So we have for each child in the school:

1. Report of examination at time of application.
2. Report of home conditions.
3. History and physical.
4. Chart showing temperature, pulse, height, weight, chest expansion and hemoglobin.

For keeping the four reports, both sides of two cards 7½ by 9¼ inches are utilized.

1. Across the top of the front of the physical examination card, with spaces for filling in, are the words: Name...., Date of Birth...., Nationality...., Address...., Age...., Sex...., School...., Grade...., Date of Admission...., Sent by...., Examined by Dr. ...., At R. P. H. A. ...., 19...., Date of Discharge...., 19...., Diagnosis...., Principal...., Examined by Dr. .... .

The remainder of the card is divided into two columns, one headed "History" and the other "Physical Examination." To guide the examiner, the history column contains the following outline: Family History—Father—Mother—Brothers—Sisters. Tuberculosis—Nervous Diseases—Alcoholism—Home Conditions—Sleeping Rooms—Boarders. Previous History—Habits—Diet—Tea—Coffee—Alcohol—Sleep—Work—Bowels—Urination. Diseases of Childhood—Venereal History. Previous Diseases—Pneumonia—Pleurisy—Rheumatism—Tonsillitis—Tuberculosis. Injuries—Operations—Present History.

The physical examination column contains the following outline: General Appearance—Nourishment—Deformities—Spinal Curvatures—Skin—Mucous Membranes—Color—Eyes—Ears—Nose—Throat—Tongue—Teeth. Heart—Apex Beat—Dulness—Character of Sounds—Regularity—Murmurs—Vessels—Pulse—Blood Pressure. Chest and Lungs—Inspection—Palpation—Percussion—Auscultation. Abdomen—Liver—Spleen—Extremities—Joints—Reflexes—Lymph-Nodes—Clinical Data—Urine—Blood—Sputum, etc.

Beneath is printed: Diagnosis........ Date.... 19...., Examiner, Dr. .. .

2. On the back of this card are columns for data under the following headings: Date; Time; Temp.; Pulse; Resp.; Weight, G., L.; Height; Chest, I., E.; Hem.; Remarks. There are twelve blank lines, and at the bottom: Teeth: Condition...., When cared for.... .

3. The front of the home investigation report card contains the following outline to be filled in: No. .., Name...., Address...., Sex...., Age...., Previous address...., Nativity...., In U. S. how long...., City...., No. in family...., Boarders, male...., female...., Health of boarders...., Father...., Mother...., Brothers...., Sisters...., Relatives ...., House...., No. rooms...., No. sleeping rooms...., Occupies front...., rear...., Adjoining houses how near...., Yard...., Balcony...., Size of child's room...., No. windows...., Open...., Closed...., Sleeps alone...., Others in room...., Sunlight...., Hours in room...., Bathroom...., Diet...., Milk...., Eggs...., Alcohol...., Does child work ...., Average weekly income...., Present income...., Means of support...., Insurance...., Rent...., Any business done on premises...., Carfare...., Towels...., Amount paid for meals per day...., Parents' attitude...., Reported to...., Reported from...., Family physician.... .

4. The back of the card is ruled with twelve lines, one for each month, with columns headed as follows: Date (with five vertical subdivisions); Summary of visits: Sick, cooperative, primary, subsequent; Remarks; Days Absent. At the bottom is a space for special notes.

After admission, the children are given a bath once a week and at that time records are taken of the temperature, pulse, weight and chest expansion. These records are placed on a chart where they may be read by all. This helps to keep the teachers familiar with the physical condition of the children. The hemoglobin is recorded twice a year.

Once a month every child in the school is seen by the physician. The patient is stripped to the waist and a general examination made. The physician has before him the record card and can usually, at a glance, tell if anything unfavorable has happened since the last examination. If any loss of weight, increase in temperature or other symptoms are recorded, a more careful examination is then made.

An office with examining table is provided for the physician, and the children can be examined rapidly, with two or three being prepared for examination all the time. In order to save time it is better to examine boys on one day and girls on another.

On certain months, special attention is given to the eyes, on another to the teeth or to spinal curvatures, and so on. We have called in specialists for consultation in selected groups of cases.

It is surprising how much can be learned in regard to a case in a very short space of time by this method.

All recommendations are noted on the chart and followed up the next month. The nurse makes notes of suggestions, and confers with the mothers if necessary. If we find that the child needs medical or surgical treatment, we have a record of the financial condition, and know whether or not the family has a private physician. If there is a family physician, we advise that the child be taken to his office, and furthermore, our suggestions are nearly always carried out. If the family is unable to secure such care, the nurse takes the child to the dispensary for treatment.

Unless the family physician advises against treatment, the corrections, as suggested, have to be made or the child is dismissed to return to the regular school. Great care is exercised that the rights of private physicians be respected.

It may seem at first glance that the records are too complete to be practical, but when it is considered that every child is supposed to be in need of special care; that we take many children predisposed to tuberculosis, from homes where the disease exists; and also that no case of actual tuberculosis is taken, it will be seen that the ordinary school examination, as to-day practiced, will not answer if results are to be obtained. Many of the cases of anemia, cardiac disease and malnutrition also need close attention.

Complete records give us a better understanding of the case and therefore add interest to the work. Records assist greatly in the treatment and save much time for the attending physician. Lastly, they are valuable for reference and as statistics after the child leaves the school. The cards are kept in individual envelopes and on file.

We have carried out this program with a nurse visiting the school once a week, and with teachers assisting at examinations; but this was unsatisfactory. Unless a physician can give several hours a week to the work, a school nurse is very necessary, if only on part time. At present we have a nurse but five forenoons a week for sixty children. The physician averages about three hours a week at the school.

We are of the opinion that a school nurse, even on part time, is one of the most valuable assets that an open air school can have.

The duties of such a nurse are: 1. To visit the homes, reporting home conditions, history of the case, etc. To advise the family as to proper hygiene and care of the child. 2. To give the children weekly baths and to record weights, temperature, etc. 3. To assist the physician at all examinations and to file the records of the case. 4. To investigate cases of absence, because irregular attendance greatly interferes with good work at the school. 5. To supervise health matters at the school in the absence of the physician.

Further duties of the school physician are: 1. To inspect the building and school rooms frequently. 2. To offer suggestions as to exercises, clothing, open windows, food, rest and in fact anything in general hygiene that may be presented.

880 Monroe Avenue.

"Final Causes" Not the Province of Science.—Science has practically given up answering whys and contents itself with describing hows. If you ask a scientific man why a stone falls to the ground, he will tell you that he doesn't know. Not long ago he would have replied that it fell to the ground because the earth and stone attract one another. This is very much the same as saying that an unsupported stone falls to the ground because, as has been ascertained by frequent experiments, an unsupported stone falls to the ground. But if you ask a scientific man how a stone falls to the ground, his intelligent countenance will light up at once and he will talk for a long time. He will talk about the acceleration of the stone, mention Newton, and say something which sounds complicated about inverse square of the distance and directly as the masses. In short, Newton's law of gravitation tells how bodies approach one another, but does not profess to say why they approach one another. There are some ingenious gentlemen, many of whom live in France, who think that is all science can do, and perhaps they are right.—*Scientific American.*

THE USE OF CITRIC SALTS IN CONGESTIVE DYSMENORRHEA

AND THE RELATION OF THE LATTER TO THE VAGOTONIC STATE

B. L. SPITZIG, A.B., M.D.
CLEVELAND

An apology seems in order for this apparent intrusion within the domains of gynecology; but the internist is so frequently consulted in reference to dysmenorrhea associated with conditions pertaining to his province, that perforce he must be adept in relieving the menstrual anomaly by virtue of general treatment.

The organic forms are herein not considered. Morbid states of the ovaries, ducts and uterus comprise definite clinical entities, often requiring surgical intervention, and yet there seems to be an associated cause in the congested endometrium itself which frequently persists after operation. How often are we chagrined to find our patient unrelieved by fixation of the uterus or dilatation of the cervical canal!

Many nulliparas who have not suffered social infection are victimized by a primary or an acquired congestive form of dysmenorrhea. Even the constitutional states may be included in the same category. Tuberculosis, rheumatism, chlorosis, gout and other diseases are associated with impaired integrity of the endometrium and predispose to congestion. The possible exceptions are the relatively few individuals deficient in hormones, the pituitary, thyroid, ovarian or suprarenal secretions.

To be brief, most non-organic types of painful menstruation, frequently complicated by sterility, may be ascribed to the one essential—congestion. Furthermore, organic conditions, as minor malpositions and moderate atresia, may be largely dependent on the same fundamental factor.

In explanation of this problem, Mosher[1] defines the physical causes. The dependence of dysmenorrhea on the erect posture, tight lacing and costal respiration is beyond question. There can be no doubt that obstruction to the return flow of blood from the pelvis is a potent cause of uterine anomalies, and the method suggested to encourage the return toward the right heart has been found to produce excellent results. Briefly, the subject is taught to exert deep, diaphragmatic movements by the forceful raising and lowering of the anterior abdominal wall.[1]

It seems, however, that we must go further in elucidating the problem. There are three chief factors concerned in the production of functional dysmenorrhea: First, a morbid condition of the endometrium. Loeb's work[2] indicates that at menstruation there is little epithelial denudation; and yet with long-standing congestion with secondary inflammation, it seems probable that clotting and other causes may induce separation to a greater or less degree. Secondly, the consequent interference with uterine contraction and obstruction to its discharge which become aggravated by uterine and cervical spasm. The spasmodic influence assumes additional importance in the vagotonic, to which reference will be made later. Lastly, the nervous element. No disorder illustrates the personal equation better than menstrual pain. Every case is individual, and there seems to be an excellent opportunity here to utilize measures toward strengthening the psychic element.

---

[1] Mosher, C. D.: A Physiologic Treatment of Congestive Dysmenorrhea and Kindred Disorders Associated with the Menstrual Function, The Journal A. M. A., April 25, 1914, p. 1297.

[2] Loeb, Leo.: The Experimental Production of the Maternal Placenta, and the Function of the Corpus Luteum, The Journal A. M. A., Oct. 30, 1909, p. 1471.

That the morbidity of the endometrium may be appreciated, brief reference is made to the changes occurring during the premenstrual stage. As a sequence to vascular relaxation, the intercellular spaces in the deeper layers become greatly swollen. The stroma cells also take part in the edema, and the glands are dilated, with infiltration of their epithelial lining and distention of their lumina with mucus and blood-cells. The superficial stratum of the mucosa allows less engorgement and remains a compact layer overlying the spongy tissues. It is believed that as a result of increased pressure, this surface epithelium becomes necrotic and is then exfoliated with the onset of the flux. As mentioned above, in recurring congestive inflammation there is greater separation of epithelium, and fibrinous membranes with thrombi are of common occurrence, characterized by varying degrees of discomfort. In the most pronounced form this represents membranous dysmennorrhea.

Over a year ago I[3] suggested that increased viscosity of the blood takes part in the production of dysmenorrhea. The causative factor is faulty hygiene, defective elimination, nitrogenous overindulgence, sedentary occupation and tight lacing. At the time of uterine congestion, the blood in this organ is more viscid, and with the accompanying stasis there is greater infiltration of serum into the neighboring tissues. This induces a change in the chemical equilibrium of the endometrial cells by causing the cellular colloids to absorb more serum and transforming this gelatinous material into a viscid mass. The effects are greater distention of the spongy layer and increased vascular stasis and mucus production, with the consequent shedding of fibrinous and thrombotic membranes. With this morbid state the ovum cannot readily engraft itself, and sterility is a frequent sequel. Reducing the viscid blood inhibits the formation of clots and membranes; stasis is diminished and excessive edema of the endometrium retarded. Bleeding through the glands is increased, and diapedesis through stroma and epithelium lessened.

In regard to treatment, nitrogenous food raises the viscosity of the blood, and accordingly is restricted before the menses. Catharsis depletes the portal circulation, and at times a hot compress is applied for the purpose of relaxation. The important procedure is the reduction of viscosity through the use of sodium citrate,[4] 20 grains three times daily, during the week or two preceding the expected period. The mode of action is peculiar to the citrates. Diuresis does not explain the results. It seems probable that the alkaline citrate neutralizes carbonic acid and other waste products and increases oxidation, thus proving to be the most efficient method for preventing cellular edema and diminishing viscosity. For the technical study of the chemistry involved in the production of edema, the reader is referred to the recent work of Woolley.[5]

The clinical evidence in support of the efficacy of this treatment is the improvement of pain and the reduction of clots and membranes in the menstrual discharge. Further, nausea, dizziness, headache and mental irritability are vastly improved.

There are types in which dysmenorrhea is an expression of the vagotonic state. Increased irritability of the craniosacral nerves leads to a higher degree of uterine and cervical spasm. Neugebauer discusses the symptoms of this vagotonic type of dysmenorrhea, and speaks favorably of the use of atropin.[6] The menses occur usually at three-week-intervals, and are profuse and painful. Other symptoms of vagotony are readily identified. The signs and treatment of this neurosis were discussed in an earlier communication[7] and in the writing of Wolfsohn.[8]

In other instances, dysmenorrhea attends the hypoplastic state with persistent thymus and frequently the incomplete forms of hypothyroidism. Sehrt[9] suggests that hyperesthesia of the genital sphere depends on protracted auto-intoxication, owing to the lack of thyroid secretion. It seems certain that thyroid insufficiency frequently coexists with the vagotonic neurosis, and the addition of thyroid extract is very effective in treating this disorder. Hertoghe[10] recommends the extract for menorrhagia in adolescence, and states that the anemic influence of the menses is thereby reduced. From personal observation, thyroid extract appears to regulate the menses in certain secretory anomalies and to reduce the intermenstrual leukorrhea. This applies particularly to chlorotics, for whom pituitary extract proves a valuable adjuvant to the thyroid medication.

At this point there is need for protest against self-medication in menstrual pain. At the earliest symptom of pelvic discomfort there is a demand for the palliating influence of alcoholic mixtures. We may well accuse ourselves of partial responsibility for this circumstance through our unwitting administration of alcohol. Practically all tonics depend largely for their effectiveness on the menstruum. More or less inactive drugs are combined with a considerable quantity of alcohol and are thus prescribed. Degradation to the proprietary is a ready sequence. Long sufferers are ready prey to enticing "wines" and "compounds." Others go further, progressing to the use of household liquors until a state of quasi-intoxication induces vasomotor relaxation and soothes the menstrual agony.

Highly intellectual women on close inquiry acknowledge recourse to their favorite remedy, an alcoholic prescription from the family physician, a much vaunted nostrum or crude liquor. The effect is similar: the alcohol is demanded when the patient is "unwell," and the habit is formed to continue during many years. When our young Americans at seminary and summer hotel are supplied by anxious mothers with whisky or nostrum, it seems incumbent on our profession to exert every effort in restraining this pernicious tendency and to prescribe appropriate measures for the replacement of alcohol in its varied disguises.

THE ABDERHALDEN REACTION *

A. A. EGGSTEIN, M.D.
NASHVILLE, TENN.

During the past year considerable doubt has been cast on the specificity of the Abderhalden reaction. Abderhalden assumes that specific ferments capable of attacking only placental tissue are elaborated as the result of the entrance of placental cells into the general circulation. He used two methods of demonstrating the digestion of the placental tissue by the serum of pregnant women; the first method was by means of the polariscope, and the second, by means of dialyzing membranes. The second is the one he recommends for clinical purposes. According to this method, the serum and specially prepared placental tissue are introduced into a dialyzing thimble, and the thimble then placed in distilled water. The mixture is placed in the incubator, and the fluid outside the thimble tested the following day for the presence of substances reacting with ninhydrin. The latter substances are supposedly derived from the placental protein as a result of the action of the specific ferments. According to Abderhalden, the greatest precaution must be taken in making the test in order to prevent bacterial contaminations, as the dialysate of the tubes showing bacterial growth will almost invariably give positive ninhydrin reactions.

Within the past year, articles have appeared in which the specificity of the reaction has been questioned, and others which deny the presence of such specific ferments. In his replies to these articles, Abderhalden states that their results are due to faulty technic, and that his assistants never fail to get positive results with serum from pregnant women and negative results with other serum.

If we accept Abderhalden's view, we must assume that specific ferments may be liberated, or generated, as the result of the entrance into the general circulation of any of the cells of the host. If this is so, what prevents the destruction of the remaining cells of the same type?

In the views which he has advanced, Abderhalden ignores entirely the antitrypsin normally present in the blood. Possibly he believes that this specific ferment is not subject to antitrypsin influence. Jobling and Petersen found that protein digestion occurs in serums containing proteolytic ferments if the antitrypsin is removed, and that these substances can be extracted by chloroform and ether, or adsorbed by treating the serum with kaolin, starch and agar. In other words, any agent which will remove the antitrypsin from a serum containing proteolytic ferments can take the place of the placental tissue in the Abderhalden test. This probably explains why Abderhalden reactions may usually be obtained with guinea-pig and rabbit serums, as these serums usually contain ferments.

Are there proteolytic ferments present in the serum of pregnant women which will attack only placental protein and which are not present in other individuals, and the action of which is not prevented by the antitrypsin normally present in the serum? To this question I must answer no. During the past year we have examined the serums of a large number of patients entering the hospital suffering from various diseases, and also a number of supposedly healthy individuals. We found that strong proteolytic ferments are rarely present in healthy human beings, but that they are present in large amounts in pregnancy, pneumonia and certain cachexias. We were able to obtain positive Abderhalden reactions in all human serums containing many ferments, regardless of the disease, not only with placental tissue, but also by extracting the serum with chloroform, or by using starch. Positive reactions were obtained with starch almost as readily as with placental tissue. In each case the serum was tested for its antitryptic strength before and after the tubes were incubated, and always found to be much lower after incubation. In those tests made with normal serums, the antitrypsin was also decreased, but the Abderhalden reaction was negative because there were no, or not sufficient, ferments to act on the exposed serum protein. While other substances will give a positive Abderhalden reaction with serum containing proteolytic ferments, placenta appears to be the best agent. It is not clear just why placenta should be the best agent for the adsorption of antitrypsin; possibly it is because there is a larger area of exposed surface.

The ferment of the serum was demonstrated in two ways. First we removed the antitrypsin with chloroform, as recommended by Jobling and Petersen, and second, added 0.2 per cent. acetic acid to the serum, as recommended by Opie. The serum was then incubated. The presence of ferments was indicated by digestion of the serum proteins. This was demonstrated by observing the increase in non-coagulable nitrogen. We have shown that the placental tissue is not digested, and that it contains as much and often more total nitrogen after digestion with positive serums than before. Further, we have found that such treated placental tissue is more resistant to the action of trypsin than the untreated. This is due to the fact that it has taken up antitrypsin.

The greatest care was taken throughout this work to prevent bacterial contaminations, and numerous cultures were made. In no instances was bacterial growth obtained. The thimbles were tested before and after making the tests, and the experiments discarded if subsequent tests cast doubt on their permeability.[1]

I must conclude, then, as a result of our work, that specific proteolytic ferments capable of attacking only placental tissues do not exist in the serum of pregnant women. Ferments are present in the blood of such individuals, just as they are in patients suffering from pneumonia, cachexias, etc., but they are not specific for any particular human protein, and are made evident only when the antitrypsin has been partially removed. A positive reaction is due to the adsorption of the antitrypsin by the placental tissue, thus permitting the ferment to act on the exposed serum protein.

The serum protein, and not the placental tissue, forms the substrate from which the substances are derived which give the positive Abderhalden reaction. This is shown by the increased resistance of such treated tissue to the action of trypsin, and also by the fact that nitrogen determinations show that the tissue is still intact.

I do not wish to intimate that the test is of no clinical value, but I do think that a negative test has more significance than a positive. The value of a positive test can be determined only when we have become more familiar with the conditions in which these pro-

---

[1] The details of the experiments mentioned above will appear in an early number of the Journal of Experimental Medicine.

teolytic ferments appear in the blood in sufficient quantity to give a positive Abderhalden reaction. The antitrypsin of the serum influences the proteolytic ferments and deserves consideration. It has been shown that in pregnancy, pneumonia and cachexias the serum has a high antitryptic titer. I believe, as suggested by others, that this would be a more reliable indication of pregnancy than a positive Abderhalden reaction.

MERCURIC CHLORID POISONING IN ANIMALS TREATED UNSUCCESSFULLY BY PARENTERAL ADMINISTRATION OF HALL'S NEW ANTIDOTE

HENRY GRAY BARBOUR, M.D.
Assistant Professor of Pharmacology, Yale University School of Medicine
NEW HAVEN, CONN.

Some attention has been given in this laboratory to a recently proposed method of combating mercuric chlorid poisoning. Hall[1] suggests for this purpose a reversal of Mayer's reaction for the precipitation of alkaloids. These substances, as is well known, form insoluble compounds with mercuric potassium iodid. Wishing to render mercury insoluble in the body, Hall proposes the employment of an alkaloid dissolved in a potassium iodid solution, and has selected quinin as comparatively harmless and readily obtainable. His solution is in the following proportions:

Potassium iodid...........	7.35
Quinin hydrochlorid.......	4.0
Water	480.0

This forms a precipitate with mercuric chlorid in dilute acids or alkaline carbonates, and should therefore compare favorably with the ordinary antidotes now given into the alimentary canal.

Greatest interest, however, attaches to its parenteral administration in the hope of fixing the mercury which has already reached the blood and tissues. This I have attempted, but with quite negative results. In like manner Kunkel[2] once attempted to cure mercuric chlorid poisoning in rabbits by causing the animals to breathe small amounts of hydrogen sulphid in the hope of precipitating mercuric sulphid in the blood; beneficial results were not obtained.

Comparing microscopically the precipitate obtained by adding Hall's antidote to mercuric chlorid with a precipitate of mercuric sulphid, one sees that the granules of the Mayer precipitate are much smaller than the mercuric sulphid granules, and therefore if formed in the blood should be much more easily disposed of by the body. But can the precipitate be formed in the blood? Unfortunately not, at least in concentrations of mercuric chlorid in the blood as high as 1:1,000. This is shown by the test-tube experiments recorded in the accompanying tabulation.

The same results were obtained whether the antidote was added in equal parts with the mercuric chlorid-serum solution or in the proportion of one antidote to three mercuric chlorid-serum.

Thus the great obstacle to the therapy of mercuric chlorid poisoning, and in fact to so many other attempts at chemotherapy, is again encountered, namely, that the poison has a far greater affinity for the tissues (for instance, the proteins and other colloids in the blood serum) than for any non-toxic remedy that can be found. Our antidote fails to detach the mercury from its firm combination.

Not relying entirely on the foregoing significant serum tests, I have made a number of experiments on mice and rabbits.

In a preliminary series of mice, subcutaneous injections of mercuric chlorid in doses of from 0.01 to 0.02 gm. per kilogram of animal were found fatal in from two to six days; 0.1 gm. per kilogram of animal killed in from two to ten hours. I therefore selected 0.05 gm. per kilogram of animal as a dose which would probably kill not immediately, but within a day or so. Six mice were given this dose (subcutaneously) at about 10:30 a. m. Three of them received Hall's antidote (in amount sufficient to precipitate all of the mercuric chlorid) intraperitoneally within an hour. All six animals were alive at 5 p. m., and all six were found dead early the next morning.

Rabbits were even more discouraging. Two were given 2.5 mg. per kilogram mercuric chlorid intravenously, followed by intravenous injection within an hour of an amount of the Hall's antidote sufficient to precipitate all of the mercuric chlorid, in two equal injections one-half hour apart. Both had diarrhea and marked albuminuria the first few days, but the one which received no antidote survived twenty-one days, and the one which received the antidote died within nine days. Similarly, two rabbits received 5 mg. per kilogram each of mercuric chlorid intravenously, and one was given a corresponding amount of antidote, dying within six hours. The one receiving no antidote survived three days.

TEST-TUBE EXPERIMENTS

	Concentration	Precipitation with Hall's Antidote
Mercuric chlorid in saline	1:100,000	(?)
Mercuric chlorid in saline	1: 25,000	+
Mercuric chlorid in saline	1: 10,000	++
Mercuric chlorid in saline	1: 1,000	+++
Mercuric chlorid in fresh ox serum.	1:100,000	none
Mercuric chlorid in fresh ox serum.	1: 25.000	none
Mercuric chlorid in fresh ox serum.	1: 10,000	none
Mercuric chlorid in fresh ox serum.	1: 1,000	none

Thus the antidote was of no help in these experiments.

When the mercury is taken by mouth, as is usual in cases of poisoning in man, it is of course impossible to say how much reaches the circulation. Within recent years a case occurred in New Haven in which a whole gram was taken and no symptoms followed, although treatment was delayed for some hours. The poison was taken after a hearty meal, which of course prevented absorption.

One decigram of corrosive sublimate, rapidly absorbed, is given by the best authorities[3] as the minimum fatal dose for an adult. So-called "cures" after much larger amounts have been taken must be attributed to vomiting, purging or some other hindrance to rapid absorption by the body, such as abundant stomach contents or gastric atony.

The foregoing results indicate the apparent futility of parenteral treatment of corrosive sublimate poisoning by such a good precipitant of mercury as Hall's solution. As an adjunct to stomach washing it will quite possibly be found equal in value to tannic acid, white of eggs, or milk, etc., which are now employed.

HUMAN SERUM IN URTICARIA *

ARTHUR W. SWANN, M.D.
NEW YORK

Although a new chapter in the therapeutics of certain diseases of the skin has been opened by the use of human serum, so little has as yet been reported that all additional information is of the utmost value. The following case of obstinate urticaria associated with joint pains and a purpuric eruption presents some points of much interest. The disease did not yield to any of the ordinary methods of treatment, and it was found that the coagulation time of the blood was markedly increased. While some of the skin reactions with foreign proteins were somewhat suggestive, none was really positive, and the elimination from the diet of the substances which gave suggestive reactions had no apparent results. Epinephrin had a temporary beneficial effect.

On account of the increased coagulation time of the blood, and the fact that this time returned to normal when a drop of fresh human serum was added to a drop of the patient's blood, it was decided to try the effects of human serum given intravenously. The patient's brother was selected as a donor after all proper precautions had been taken, and six intravenous injections of his serum were given, a total of about 100 c.c. There were no bad effects from the serum. The longest interval between doses was twenty days. The patient has had no hives since the fifth injection, seven and one-half months ago, the coagulation time of the blood has been normal and she has felt better generally than for many years.

The literature on this subject is very brief. It is not necessary to review it here as this has been quite recently done by Fox,[1] Gottheil and Satenstein[2] and Hilario.[3] There is still much work to be done on this subject, in regard to the kind of serum of most value, the number of injections and the dosage. The case given here merely shows results in one type of case and with one method of treatment. The whole question of just how the serum acts remains quite unsolved.

In investigating other cases of urticaria in this connection, it has become apparent that they are certainly not all associated with an increased coagulation time of the blood, but that there are other factors at work.

REPORT OF CASES

History.—C. B. S., widow, aged 45, seen first, Feb. 25, 1914, complained of attacks of hives for eight months, with itching, pains in the joints and purpuric spots. The patient's father died of sarcoma. There was some rheumatism in the family. Otherwise the family history was negative. The patient was a small eater, and her habits of eating were regular. She had taken no coffee since onset, two cups of tea a day, and no alcohol. She took eggs about once in three days, cheese every day or two, usually cream cheese, occasionally Roquefort, but no cakes. She always took pepper on eggs but rarely on any other food. She ate meat once a day, no tomatoes, and no strawberries, as they bring out "red marks" on the skin. The average weight was 130 pounds, but the patient had lost weight recently. She did not take much exercise since onset, but before that a lot. She was not sleeping well and was taking adalin. Menstruation was irregular. There were no children, and there had been no miscarriages.

The patient had had mumps. Seven years ago, the right tube and ovary and the appendix had been removed. The operation had been followed by postoperative pneumonia. Two years ago she had a small tumor removed from the breast. There had been no recurrence. The patient had never been very robust. Eight months ago while in California, the patient was ill all one night with vomiting and diarrhea. Next morning she was covered with hives. There had been one very slight attack years before. She thinks that the attack eight months ago was due to eating oysters. No one else in the party was ill. Since then she has had six or seven attacks of urticaria, although she has been on a diet which excluded shell-fish and fruit and allowed only a little meat. At one time she had only rice for five days. In the intervals between attacks she had felt quite well. There was no asthma in the family and the patient had had none. The hives were accompanied by intense pain as well as itching, and were generally especially painful on the soles of the feet. During the attacks and afterward she suffered from grip-like pains in the bones of the legs and spine and at times in the joints. With the attacks purpuric spots were common, especially about the elbows and knees. The eyes and lips swelled. The appetite was never good. The bowels had been very costive since onset, but before that, fairly regular. Urination had been very frequent for the past two weeks, with some tenesmus. Formerly the patient did not have to get up at night, but now she had to two or three times. She was drinking a great deal of water. The interval between attacks was three or four weeks. The attacks were not becoming worse or more frequent. She was just recovering from an attack which kept her in bed for eleven days, and has been up for the past five days. The nose bled easily and frequently and always when the patient was on a high mountain.

Physical Examination.—The weight was 116 pounds. The patient was somewhat nervous. The color was good. There was no eruption. There was a very slight fulness in the region of the thyroid. Heart: The left limit of dulness was 11 cm. to the left of the midline in the fifth space. There were no murmurs. It was normal except for slight accentuation of the aortic second sound. The arteries were just palpable. The blood pressure was 145 and 85, the rate 85, regular. The rest of the examination was normal. The urine was pale, acid, specific gravity 1.011, and contained a trace of albumin, but no sugar or indican. There were few leukocytes, epithelial cells and hyaline casts. Blood examination revealed hemoglobin, 80 per cent.; spread appeared normal. There were no eosinophils.

Course.—March 2: Skin reactions with horse, rabbit and hen serums and egg albumin were all negative. Reactions with coffee, buckwheat flour and oysters were slightly suggestive. Milk showed a small wheal and marked erythema. The patient was put on a diet of fruit, green vegetables, potato and cereals without milk, and iron and strychnin tonic. The blood pressure was 150. The coagulation time (slide method), complete, was fifteen minutes.

March 4: Skin reactions with beef serum, sheep serum, buckwheat, milk, raw halibut and cooked halibut were all negative. Coagulation time (Brodie method) was from twelve to seventeen minutes; control, five minutes.

March 6: 1. Coagulation time (Brodie) was from seventeen to eighteen minutes. 2. Blood + calcium chlorid, 5 per cent. in normal salt solution, was unclotted in thirty-one minutes. 3. Blood + a small drop of normal human serum, twenty-four hours old, resulted in coagulation in seven minutes. 4. Human serum, diluted 1:10 with saline + patient's blood, resulted in coagulation in seventeen minutes. 5. Human serum, diluted 1:5 with saline + patient's blood, resulted in coagulation in ten minutes. 6. Undiluted serum + patient's blood, as in 3, resulted in coagulation in seven minutes. These tests were repeated by the slide method with approximately the same results. Skin reactions with buckwheat and coffee were negative. Milk was suggestive.

---

* This work was done by Dr. Swann during the first half of 1914, his death preventing its continuation and his investigation of other cases of urticaria along this and other lines. On this one case, however, he left complete notes, from which this report has been written. It has been necessary only to wait a sufficient length of time and to make a few final observations in order to be sure that the good results have persisted.

2. Gottheil, W. S., and Satenstein, D. L.: Autoserum Injections in Certain Obstinate Dermatoses, Med. Rec., New York, 1914, lxxxv, 620; The Autoserum Treatment in Dermatology, The Journal A. M. A., Oct. 3, 1914, p. 1190.

3. Hilario, J. S.: A Contribution to the Autoserotherapy of Certain Diseases of the Skin, Jour. Cutan. Dis., 1914, xxxii, 780.

March 8: The patient felt better. There had been no hives for three days. The diet had been increased. Milk, coffee and pepper were the only articles prohibited.

March 13: There was an attack of hives this morning with pain, swelling and redness of the left thumb joint. Blood pressure was 135. Weight was 117. Blood-platelet count was 200,000. The coagulation time by both the slide and Brodie methods varied between fourteen and seventeen minutes. The coagulation time of blood + old human serum was the same, but the clots were firmer and more solid.

March 23: Coagulation time was nineteen minutes. The patient felt and looked better. There had been no hives since the last note. The weight was 119 pounds, blood pressure 145. The patient began taking cod-liver oil March 19.

March 30: The patient had had hives every day off and on for five days. The coagulation time was from sixteen to nineteen minutes. The weight was 120 pounds. The patient had moderate hives last night with a swollen and painful finger. Report on stool of March 25 was: Dark brown, pasty mass. No mucus. Faintly acid. No blood. Urobilin moderate. Carbohydrate fermentation considerable. Trypsin moderately diminished, digestion in twenty-four hours. Amylopsin normal. Microscopic examination revealed no pus or red blood cells; no ova or parasites; many muscle fibers showing marked striations; many fatty acid crystals; few fat globules and very little starch. Smears showed Gram-positive organisms present in about 50 per cent. of the total number.

April 6: There were moderate hives last night with swollen and painful finger and elbow. Pain was severe to-day. The coagulation time was nineteen minutes, after epinephrin, fourteen minutes. The blood pressure was 138. Five minims of epinephrin were given.

In seven minutes pain and stiffness were better. Blood pressure was 130.

In ten minutes there was no pain. Stiffness was better but numbness persisted.

In seventeen minutes numbness was less. Blood pressure was 130.

In twenty-five minutes numbness was worse again. Blood pressure was 125.

In seventy-five minutes pain returned again in the finger and thumb. Seven minims of epinephrin were given.

In four minutes the pain was better. Blood pressure was 125. In eight minutes the pain was gone.

In ten minutes the pain returned to a slight degree, but did not become severe. Four hours later the pain was practically gone. There was slight numbness in the fingers. Blood pressure was 138.

As the patient continued to have hives throughout the preceding period of observation, it became necessary to find some means of relieving her. Careful diet had had no appreciable effect. Owing to the fact that the patient's coagulation time was considerably prolonged and that the addition of human serum to her blood made the coagulation take place in approximately normal time, the idea of the intravenous administration of human serum presented itself and was decided on. At the time it was not known that this had been previously done in one or two similar cases. Accordingly, her brother's blood was tested in every way and found suitable.

April 7: One c.c. of the brother's serum was injected subcutaneously. As there was no reaction in forty-five minutes, 8 c.c. of the same serum was injected intravenously. There was no reaction.

April 15: Coagulation time was from twelve to fifteen minutes. Twenty c.c. of the brother's serum were given intravenously. One hour later the coagulation time was fifteen minutes. On the day following the first injection the patient had a slight attack of hives which vanished spontaneously. There were none again until April 11, when she was awakened by hives and had pains in the fingers. The attack lasted three or four hours, and was so bad that 5 minims of epinephrin were given. In about half an hour the hives were completely gone. They returned in twelve hours, but disappeared immediately on repetition of the epinephrin. April 12, the patient had an attack in the morning and in the evening, each attack yielding promptly to epinephrin. There had been no recurrence until this morning, when there was an attack with pain. In fifteen minutes after 5 minims of epinephrin had been taken, all symptoms disappeared.

April 17: There had been no hives since April 15. The patient felt better and stronger. Coagulation time was from twelve to fifteen minutes.

April 22: The patient had been well and had had no hives until April 19, when they suddenly appeared during the day and persisted until 10 p. m. During the evening of April 20 the patient had some red blotches but no wheals. There was little or no itching. April 21 blotches again appeared, but they were not severe. To-day the blotches had been worse. There had been no pain since the last injection of serum. The third dose of serum was given to-day, 20 c.c. intravenously.

April 23: The patient had hives yesterday until bedtime, when they disappeared. She is much better to-day. There are no hives or itching. The fourth dose of serum, 20 c.c. intravenously, was given. This serum was thirty hours old. Half an hour after the injection the coagulation time was from seven to nine minutes.

April 27: The patient felt much better. There had been no hives, itching or pain since April 22. The coagulation time was ten minutes, the weight 120 pounds.

May 8: There had been no hives until May 1, when the patient had a mild attack late in the evening, not bad enough for epinephrin. They did not keep her awake. There was a slight recurrence May 2, and on the following day they were worse and accompanied by pain in the fingers and toes. Since then the patient had had slight attacks off and on. She felt very well. This weight was 124 pounds, the coagulation time ten and one-half minutes.

May 13: There had been no hives since May 8. The patient felt very well. The coagulation time was fifteen minutes. The fifth dose of serum, 20 c.c., intravenously, was given.

May 14: The sixth dose of serum was given to-day, 10 c.c. intravenously.

May 15: The weight was 124 pounds. The patient felt very well. There had been no hives since May 8. The coagulation time was twelve and one-half minutes.

May 21: The patient felt very well. There were no hives. The coagulation time was seven and one-half minutes.

June 4: The patient felt very well. There were no hives.

June 13: The patient was perfectly well. There was no suggestion of hives. The coagulation time was four minutes, control six minutes. The blood pressure was 160.

June 23: The patient, June 20, had eaten part of a radish. Almost immediately it began to "repeat," and she had cramps, then diarrhea and a little indigestion until yesterday. June 22 she had a few little red spots on the hand, foot and about the waist. They were very few and not like hives. She also had some pains in the joints. To-day the spots had disappeared, but there was a little tenderness in the joints of the hands and feet, but nothing else. The coagulation time was four minutes. Control from 5 to 6 minutes.

October 11: The patient had had a fine summer and felt very well. She had had no hives. There had been an occasional twinge of pain in her joints. The coagulation time was four and one-half minutes.

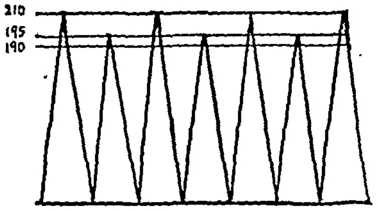
Conservation of Resources.—The real thing that we have to conserve in America is the American people, their energy, their elasticity, their originative power, their capacity to hope and to achieve.—Woodrow Wilson, quoted by Irving Fisher, Memorial Relating to the Conservation of Human Life.

PULSUS ALTERNANS DETECTED BY THE SPHYGMOMANOMETER

JAMES B. HERRICK, M.D.
CHICAGO

It is a matter of common observation that in many conditions, notably cardiac arrhythmias, the sphygmomanometer will often detect the fact that in a given heart the beats may vary in strength, some strong beats pushing through to the artery at the wrist, though the pressure of the manometer cuff is sufficient to cut off all those that are weak or of average power. The arrhythmia of mitral stenosis when auricular fibrillation has set in is a good example. In the hypertension of chronic nephritis or of arteriosclerosis, the same phenomenon may be encountered.

When the systolic pressure is being tested in a patient in whom an alternating pulse is present, a manometer pressure may be reached that cuts off every other beat—the weaker beat—thus halving the rate of the pulse at the wrist. Increasing the pressure on the brachial artery, by still further inflation of the cuff, of course blocks all the beats. Then slowly letting out the air, the point is reached at which the stronger comes through; when still more air is allowed to escape, another point is met where the alternate, weaker beat is perceived, thus doubling the pulse rate, that is, reestablishing the original rate. The difference in strength between these beats, when thus controlled by the sphygmomanometer, which exerts a pressure just below the maximal pressure for the weaker beat, is relatively great, and this difference is plainly perceptible to the palpating finger on the radial artery. The test may also be made by the auscultatory method of using the blood-pressure apparatus.



At 210 mm. Hg, no pulse is felt at the wrist. Below 210 and above 195, the stronger beat is felt. Below 195, for example at 190, the pulse rate doubles and the beats are alternately strong and weak.

As illustration, a man of 45 with large heart, cardiac asthma at night, albumin, casts and albuminuric retinitis, clearly has a high blood pressure. No irregularities in the rhythm or difference in strength of the pulse beats are made out by ordinary palpation of the radial artery. The pulse is 80 to the minute. When the pressure of the manometer reaches 195 mm. of mercury, the radial pulse drops to 40 and remains at that rate until 210 mm. is reached, when it disappears. On testing in the reverse order, above 210 the beat at the wrist is lost; from 210 down to 195 the strong beats come through at the rate of 40 per minute; below 195 the beats are 80 per minute, the new, added beats being perceptibly feebler than those coming through at 210 (see diagram). The pulse is clearly of the alternating character, and the sphygmomanometer shows what the finger alone at the wrist could not detect. At times the stethoscope, sphygmograph, polygraph or electrocardiograph may be necessary to decide as to whether the condition is due to dicrotism, extrasystole, etc.; but in most cases the alternation of the pulse can be made out in the manner described. The information afforded is not always essential, yet it is of help in making a prognosis, the pulsus alternans being rightly regarded as often an evidence of serious impairment of the muscular efficiency of the heart.

So far as I know, this method has not been described by others. If it has, my reference to it will, by repetition, emphasize a simple yet fairly satisfactory means of detecting pulsus alternans.

122 South Michigan Avenue.

RUPTURED APPENDIX AT FULL TERM PREGNANCY

C. J. Wallace, M.D., Duluth, Minn.

Mrs. E. J. P., aged 24, German, housewife, married six years, mother of two children, aged 4 and 2 years, had typhoid three years ago. She has had recurrent attacks of appendicitis during the last two years, all very slight, however, and none during the previous eight months.

I was called on Saturday night, April 19, 1913, to attend the patient, as she had expected, during childbirth. On my arrival at her home I found my patient sitting in a chair with her hands over the lower abdomen and complaining of severe pain down low, especially over the right side. She was placed in bed and prepared, and an examination made of the cervix, which showed a slight degree of dilatation, about ¾ inch; the head was not engaged, however, and I felt certain, as the result of my examination, that there would be no need for my services for some time. I went home, leaving orders to be called if any change seemed to take place. I was not called again until Sunday afternoon at 3 o'clock. I found my patient still in severe pain and learned that she had been so ever since I had left her the day before. She had a temperature of 103.6 F.; the pulse was 128. I then made a thorough examination and found the cervix just about as it was at the time of my previous examination, but, on closer survey with my finger, I thought I felt, through the wall of the vagina, what seemed like an abscess located in the region of the appendix. I covered the ground very thoroughly and made a diagnosis of suppurative appendicitis with possible rupture of the appendix.

The patient was removed to St. Mary's Hospital and placed in bed with ice-caps over the appendiceal region, with the hopes of preventing any further trouble until after the child was born. On Monday, however, the conditions were no better, and with the temperature at 104, pulse 140, and slight dilatation, I could see no other way out than to go in and relieve the abscess and drain, at least. At 1:30 p. m. Monday I operated, doing a complete appendectomy, and cleaned out the pus which had formed freely about the much enlarged vessels and ligaments which are at this stage of pregnancy far from the size we generally find them. Hoping to avoid later trouble I placed a rubber tube drain in the culdesac and one in the groin. The incision was closed tightly around the drains, especial care being taken to close the fascia so as to get a good union and avoid separating during the severe strain which was sure to come at the time of childbirth. It was quite difficult to get these parts together, and would have been impossible had I not made a transverse incision through the fascia, a fact which, I think, saved the situation.

Tuesday morning the temperature was 99.3, pulse 88. At noon the labor pains began, and at 12:30 p. m. the patient was put to sleep and an 8 pound 6 ounce boy safely delivered. We had no trouble with the wound. Everything kept its place. The following day the patient complained of severe pain in the right side, due, I think, to the operation and the large drainage tubes, which were still in place. Considerable pus drained from the wound, but the temperature remained about normal and the mother went on to complete recovery. She left the hospital May 4, together with her baby boy.

One thing was very noticeable, and that was the dislocation of McBurney's point in "so pregnant a woman." It calls for some close calculating in locating the point for incision.

Preventogram.—Good food, well chewed, is better than much food quickly bolted.—*Buffalo Sanitary Bull.*

B. DEPRESSANTS: 5. OF THE HEAT CENTERS—(Continued)

ANTIPYRETICS AND ANALGESICS

ACETANILID, ANTIPYRIN AND PHENACETIN GROUP

The introduction of the antipyretics and analgesics of this group affords one of the most interesting chapters of medical history. The high cost of quinin, which resulted in its adulteration, led to efforts to discover a method of preparing it synthetically, and in addition to the cost of the alkaloid, its bitter taste, and its relative insolubility, which interfered with its use by subcutaneous injection, served as a stimulus in the search for a substitute for it. While these efforts were unsuccessful so far as the immediate aims were concerned, they did lead to the discovery of numerous synthetic compounds, including the antipyretic analgesics which have come into use during the past thirty years. Curiously, the best drugs of this group were among the earliest discovered, and the exploitation of the newer members has been largely mercenary.

Quinolin was used as the starting-point in the search for synthetic quinin or a substitute, because it results from the decomposition of quinin, and it retains the antipyretic action of the parent substance, but it is too toxic for therapeutic use.

Kairin and thallin were among the first of the synthetic antipyretics; they soon dropped out of use because of their toxicity. Antipyrin was prepared in 1884 by Knorr, who used phenyl-hydrazin as the starting-point, and who supposed that antipyrin contained two quinolin rings. It is now known to be phenyl-dimethyl-pyrazolon.

Anilin was known, as far back as 1861, to have antipyretic actions, but its toxicity precluded its therapeutic use, and the attempt was therefore made to utilize its antipyretic action while reducing its toxicity by introducing various radicals into the molecule. Acetanilid, which results from the introduction of an acetic acid radical into the anilin molecule, was one of the earliest of these synthetic anilin derivatives, and it continues to be the cheapest and one of the best.

Paramidophenol, very closely related chemically to anilin and phenol, was found in the urine after the administration of one of the antipyretics, and this led to its use as a starting-point in the preparation of synthetic substitutes for the older members of the group. The introduction of an ethyl group into the paramidophenol forms phenetidin, and the introduction of an acetic acid radical into this forms acetphenetidin, or, as it is commonly called, phenacetin.

The antipyretic and analgesic actions of the drugs of the acetanilid and phenacetin type result from certain compounds, such as paramidophenol, which are split off in the body from the parent drug. If they are split off too rapidly the action is too violent, and if they are split too slowly the action is too feeble; hence the therapeutic value of a member of this group depends on a gradual splitting of the drug in the body. Innumerable compounds may be formed by the introduction of other aromatic acid radicals in place of the acetic, or other alkyl groups in place of ethyl, but none of these has proved superior to acetanilid and phenacetin. Some are split very slowly and therefore have very little toxicity, but they are also less active therapeutically, and some are more active therapeutically, but are also more toxic.

Fraenkel says that no cheaper and better substitute for antipyrin and phenacetin can be prepared from the parent substances, and that it is purposeless to continue to multiply these. While we should continue to search for improved antipyretics and analgesics, such improvement can come only with development along wholly different lines.

The various members of the group have closely similar actions, but they show considerable quantitative differences in activity.

Their classification as fever narcotics indicates their depressant action on the higher parts of the brain, and in addition to their depression of the heat-regulating centers, it is probable that they cause an actual paralysis of certain paths concerned with the perception of pain, because even small doses are usually as effective as larger ones in relieving certain forms of neuralgia. They have a slight tendency to induce sleep, and this tendency becomes more pronounced when one remains quiet after relief from headache or other pain, but the mental faculties may remain alert when one exercises them after the relief of headache.

Large doses cause collapse, with disturbance of the respiration and circulation. The heart may become feeble and death may result from cardiac failure, but this is rare, and it never occurs after acetanilid, antipyrin or phenacetin, except when overdoses are taken by enfeebled patients, or excessive amounts by those suffering from minor illness.

Severe, but not fatal, collapse is not infrequently seen after moderate amounts of these members of the group which are decomposed more rapidly than the three members just mentioned. If such rapidly acting members of the group are used, it would be better to employ minimal doses and repeat these more frequently than with the more slowly acting ones, but there seems to be no reason for their continued use.

These drugs do depress the heart somewhat, but this action is overrated by manufacturers of nostrums who claim that their preparations lack this cardiac effect because it is overcome by the addition of caffein or other supposedly antagonistic substance. Curiously, caffein and the antipyretic analgesics of this group have a synergistic action on the heart; hence large doses of such compounds are, if anything, more dangerous than the drug which they are intended to displace.

The antipyretic analgesics produce cyanosis when large doses are used, or when the smaller doses are used continuously, and since they were known to injure the heart to some exent, it was supposed that this injury sufficed to explain the cyanosis. We know that the cyanosis is usually due to the formation of methemoglobin by the products of decomposition of the antipyretics, and the more rapidly they are decomposed in the body, the greater is the action on the hemoglobin. The milder actions leave the corpuscles intact, but with the more violent action the corpuscles are broken down. This does not take place when the drugs are mixed with blood in a test-tube, because the drugs are not then decomposed.

---

* This is the eighth of a series of articles on useful drugs—on practical pharmacology for the general practitioner. As soon as completed, these articles, elaborated by additional subjects, will be published in book form.

Those antipyretics of this type which are devoid of the action on the blood are also therapeutically useless, because the paramidophenol, or analogous substance, which causes the formation of the methemoglobin is also responsible for the antipyretic action and only those which are decomposed too slowly to exert a pronounced antipyretic and analgesic action are devoid of the action on the blood.

The antipyretics cause dilatation of the vessels of the skin; this promotes sweating, which is useful in the reduction of temperature; in case this is excessive, atropin should be administered in small doses.

The antipyretics, like narcotics in general, lessen metabolism and therefore the production of heat, but this is of much less importance than their action on the heat-regulating centers, for, as previously stated, it is through their influence on the loss of heat that the temperature is regulated for the greater part.

ABSORPTION AND EXCRETION

Antipyrin is very soluble in water, while acetanilid and phenacetin are only slightly soluble, but all are absorbed fairly readily from the gastro-intestinal canal, and are nearly always administered by the mouth.

The rate of excretion appears to depend on the rate of decomposition to a certain extent, and none of the drug appears in the urine unchanged after the taking of moderate amounts of acetanilid, which is decomposed more rapidly than phenacetin.

When the urine of a patient who has taken one of these drugs is exposed to the air, it may assume a dark color because of the oxidation of certain of the decomposition products.

THERAPEUTIC DOSES

The antipyretic analgesics are not used so frequently as they were formerly for the reduction of body temperature alone, but they are used in much the same conditions for the relief of pain, such as that occurring with influenza; for headache, which accompanies so many types of fever; and to allay nervousness, thereby securing rest and sleep which are essential for the patients' well-being and the want of which is so injurious to the heart and nervous system.

They are sometimes used for the reduction of fever, when this is excessively high, but even in such cases the benefit derived is probably due mainly to one or more of the actions just mentioned.

They are widely used for the relief of headache arising in the greatest variety of conditions. They sometimes afford prompt relief with small doses, and often fail even when large doses are used. In fact, if a small dose fails to relieve headache or neuralgia a large dose seldom accomplishes this.

The wide-spread use of these agents by the laity for the relief of all forms of headache and neuralgia and for pain which often attends menstruation should be discouraged because of the danger of their indiscriminate use, and especially because of the frequency with which overdoses are used in unsuitable cases. The patient who has once obtained relief through the use of a given drug supposes that subsequent failure can be explained only on the basis of his having taken an insufficient amount, with the result that he repeats the dose many times. There is also the danger of the formation of the habit, whenever the drug is used in chronic conditions attended with headache or neuralgia.

Antipyrin is applied locally in concentrated solution as a styptic in hemorrhage of the nose. The antipyretic analgesics have a more limited field of action than morphin, being of little value in pain due to inflammation, but they deserve the preference over opium and morphin in those conditions, such as neuralgia, which they do relieve.

They should be used with caution in debilitated patients in whom the danger of collapse is exceptionally great. Some persons show an idiosyncrasy toward them and exhibit rashes or exanthemas after even moderate doses.

DOSAGE

The average dose of acetanilid is 0.2 gm. (3 grains), but it is better to use an initial dose of 0.1 to 0.15 gm. (1½ to 2 grains) and repeat cautiously when necessary. Antipyrin is given in slightly larger amounts, the average dose being 0.25 gm. (4 grains), and phenacetin is used in somewhat larger doses than antipyrin, the full dose being 0.5 gm. (8 grains), but it is seldom necessary to give more than 0.3 gm. (5 grains) for the relief of neuralgia or headache. The latter dose may be repeated at intervals of three hours until several doses have been taken when necessary. All of the antipyretics are more effective in reducing the temperature if given during a natural remission, and the later in the course of the remission, the smaller the dose required for a given effect.

It is probable that there is little difference in the danger of the several antipyretics mentioned above in the doses given. There is no question, however, that phenacetin is the least dangerous in equal amounts, but since it is also the least active therapeutically, this does not constitute an advantage with the proper regulation of the dosage. Many of the older and some of the later posologic tables give doses of the antipyretic analgesics which can hardly be considered entirely safe. While such doses may be used in certain cases, they are not to be recommended for routine procedure.*

PROPRIETARY PREPARATIONS AND MIXTURES

The Council on Pharmacy and Chemistry gave its attention soon after its organization to several of the more widely advertised mixtures which were then claimed to be synthetic preparations. These preparations were found to be simple mixtures of acetanilid, caffein and sodium bicarbonate or other alkalies, and usually contained small amounts of tartaric or citric acid. The mixtures cost about 2 or 3 cents an ounce and were commonly sold for a dollar an ounce at wholesale. Since the enactment of the food and drug law in 1906 the composition of some has been changed, acetphenetidin being used in place of acetanilid. This further emphasizes the fact that manufacturers of nostrums are in business primarily for profit, with little or no consideration of the interests of the consumer or of the physician who is utilized as an advertising medium for the several preparations.

No one will deny that mixtures containing coal-tar analgesics relieve pain in many cases. Since they are all sold direct to the public, the danger resulting from self-medication is obvious, because it has been definitely shown that mixtures containing caffein and one of the antipyretics requires a special caution in their use. It is unfortunate, to say the least, that the Pharmacopeia of the United States should have countenanced these mixtures to the extent of having recognized the compound acetanilid powder which is one of this type.

---

* Owing to lack of space the materia medica of acetanilid, acetphenetidin and antipyrin is omitted. It will be included when the series is published in book form.

In addition to these pretended synthetics, which are unworthy of further consideration, there have been introduced innumerable synthetic preparations of the general type of phenacetin or acetanilid with some added advantage, but unfortunately such advantage is invariably offset by disadvantages. For example, when one of these preparations is less toxic it is also invariably less active therapeutically. It is unnecessary to discuss these substances in detail, for, as we wish to reiterate, there is none which deserves the preference over acetanilid, antipyrin and phenacetin.

DIPHTHERIA (CONTINUED)

F. Care of the Heart

Although it was long considered that heart failure in diphtheria was due to vasomotor paralysis, or to action on the vasomotor center, it has been shown by Porter and Pratt[1] that such is probably not the case: that heart failure is probably due to the action of the toxins on the heart itself. Dr. F. W. White of Boston long ago[2] showed that the heart was frequently affected more or less seriously in diphtheria. White also quotes many other authorities showing that myocarditis is not an infrequent complication, that valvular disease may occur from diphtheria, and that even a chronic myocarditis may persist, or a valvular lesion may persist for months or even years, or for life. White and Smith studied the hearts in a thousand cases of diphtheria, and came to the conclusions that moderate disturbance of the heart is very common in diphtheria, and that persistence of cardiac defects often lasts from two to six months; but generally cardiac disturbances from diphtheria become permanently cured. The mitral valve is the one most frequently diseased, and if a lesion is caused, it is generally insufficiency. About 60 per cent. of the patients with diphtheria show an irregular pulse, and the younger the patient, the more liable he is to have this heart irregularity. It may occur even in mild cases. These investigators found that out of 1,000 cases 878 had a heart murmur of some kind at some period of the disease, either at the apex or at the base. The murmurs were generally systolic. These murmurs usually clear up and are not generally significant of valvular lesions. The murmur at the apex is doubtless due to a relative insufficiency of the mitral valve, because of slight dilatation of the left ventricle. In this investigation, necropsies showed that endocarditis and pericarditis are extremely rare complications in diphtheria.

Dr. G. M. Smith[3] reviews more recent investigations, made on the hearts of diphtheria patients. He quotes Rohmer as concluding that in diphtheria, pathologic changes may occur in the auriculoventricular bundle, but that there is no specific action of the diphtheria toxin on the bundle of His. However, diphtheria toxins may so affect the connecting bundle from a functional point of view that heart-block can be produced, even without demonstrable anatomic lesions.

Clinically, the gallop rhythm, with or without vomiting and epigastric pain and tenderness, is a bad symptom in diphtheria. This gallop rhythm of the heart is very serious, and if accompanied by vomiting, the prognosis is very bad. Hume and Clegg,[4] after an investigation of 573 cases of diphtheria, declare that any form of arrhythmia of the heart (except sinus arrhythmia) in diphtheria indicates that the heart muscle or nerves are pathologically disturbed. This may occur even when the diphtheria is apparently mild.

After a patient is apparently well from diphtheria, if he has been severely ill, and especially if the case has been neglected and a large amount of toxins have been absorbed, cardiac failure may occur any time from the second to the fifth week. Symptoms of late cardiac weakness are often a slow, weak pulse. Such hearts, however, become rapid on the least exertion. Such patients are often very pale, and there are liable to be more or less gastro-intestinal disturbances.

There can be no question that the effects on the heart in diphtheria are due to the Klebs-Loeffler bacillus toxins; consequently, if antitoxin in sufficient dose is given early, the toxic effect on the heart will probably rarely occur. Consequently, cardiac deaths in diphtheria will be less and less frequent with the early proper administration of antitoxin.

The most important treatment of cardiac complication is rest, and prolonged rest. A patient who has shown cardiac inflammation of any kind, or cardiac irritation during diphtheria, should have a prolonged rest in bed and a very slow convalescence. The small dose of strychnin suggested above as a nerve stimulant is probably sufficient. If the heart is very rapid, it may be unwise to give even this small dose. Larger doses do not seem to raise the blood pressure during illness, and strychnin in large doses as a cardiac tonic, in prolonged weakness, is not so successful as has been thought. In an apparently acute failure, a fair-sized dose, 1/40 grain for a child 10 years old, may be given hypodermically; but to persist in large doses of strychnin is inadvisable. Digitalis is not indicated, and alcohol should not be given. Caffein and camphor may be worth while; but the main thing is absolute rest, small amounts of food, the least possible disturbance for bathing, feeding, defecation and urination, and no prostrating purgatives.

G. After Rest

A patient who has recovered from diphtheria, however mild it may have been, should have, for the first two weeks, at least, a carefully watched convalescence. Strenuous exercise should be avoided, and the heart should be carefully examined before the patient is allowed to return to his usual work, school, or play.

H. When to Raise the Quarantine

This has already been sufficiently discussed. Boards of health vary in their requirements. The safest rule would seem to be to release the patient from quarantine after four negative cultures have been taken, each one two days apart; one of the cultures should be taken from the nostrils. The swab specimens should be procured by a physician, and should be taken several hours after any antiseptic gargles have been used. Also the last culture should be taken from back of the tonsils and from crypts, if any are present.

I. Fumigation

As stated, formaldehyd or other fumigation is unprofitable in diphtheria, but may be added to thorough germicidal cleaning of the room and its contents. This is a decision for the local board of health.

J. Paralysis

With the early injection of a sufficient dose of antitoxin, diphtheria paralysis will become less and less frequent. The paralysis of the soft palate, which used to be so frequent, is already becoming infrequent. This paralysis occurs early, between ten and twenty days from the beginning of the illness. The treatment consists of tonics, small doses of strychnin, the best of nutrition, fresh air, sunlight, rest, and prolonged convalescence. The general paralyses, which are now rarely seen, were more serious, and occurred later. They are slow in recovery, and besides general treatment, require massage and electricity.

K. Diseased Tonsils

Quite probably diseased tonsils cause a susceptibility to diphtheria, as they certainly do to follicular tonsillitis. After complete recovery from a diphtheria attack, when the general condition is perfect, and the heart is in good condition, operations should remove all portions of tonsils that show disease. Whether complete enucleation should be done, or only diseased portions should be removed, and whether or not the capsules should be left, are subjects for an expert decision.[5]

LARYNGEAL DIPHTHERIA

Membranous croup is laryngeal diphtheria, and as soon as the diagnosis can be made that there is exudate in the larynx or laryngeal region, antitoxin should be given in large dose, without waiting for a decision from the laboratory that the Klebs-Loeffler bacillus is present. The only safe place for a patient with laryngeal diphtheria is a contagious disease hospital, where expert skill in intubation and, if necessary, in tracheotomy can be quickly obtained. The main danger from diphtheria in this location is suffocation.

The toxemia is not great, and the absorption is much less than in nasal, nasopharyngeal, or even in tonsillar diphtheria.

The best of nutrition is important, as exhaustion from labored breathing is likely to occur. The atmosphere of the room is better moist, on account of the membrane becoming dry and causing more obstruction before it loosens and is coughed up. Just how much local steaming of the throat, or inhalation of various medicated solutions should be given, is to be decided by the individual physician. The main advantage is doubtless from the vapor of water.

The main requirements to be remembered in laryngeal diphtheria are the administration of an immediate large dose of antitoxin; intubation by a skilled operator as soon as indicated; a trained nurse skilled in intubation cases, if such can be obtained; the ability to recall quickly the physician who intubated if the tube is coughed up; the immediate removal by the nurse of the intubation tube if it plugs up, and the quick performance of tracheotomy by the surgeon, if such a measure is needed.

SEPTIC SORE THROAT

For some years there have been reported in England epidemics of septic sore throat, some of which have been distinctly traced to infected milk, and all of which probably develop from that source. In the last few years several cities and towns in this country have suffered from epidemics of this character, and in every instance it has been traced to milk from one dairy, and ultimately to one or more diseased cows. The disease that causes such infection is an inflammation of the milk glands, a mastitis, or an inflammation of the udder termed garget. Another possible source for the dissemination of this germ is an infected throat of the milker, or of some one who handles the raw milk.

The germs found in the inflamed udders, in the raw milk, and in the throats of those infected are the same, namely, the *Streptococcus pyogenes*. The largest epidemics have occurred in Boston, Baltimore and Chicago, and in all, about 25,000 individuals have been attacked. The death rate is small, and is due to complications. An epidemic occurring in Boston is described by Winslow,[6] the Chicago epidemic by Capps,[7] and an epidemic in Courtland and Homer, N. Y., by North, White and Avery.[8]

The clinical symptoms have been the same in all of these epidemics, and Capps states that the throats generally show intense hyperemia without a grayish exudate. The cervical lymph glands enlarge, and may suppurate; there is extreme prostration, and a tendency to relapse. The complications are inflammation of the middle ear, abscess around or about the tonsils, and erysipelas or other skin eruptions. The most dangerous and fatal complication is peritonitis, and there may be fatal septicemia, with localization in the lungs. Endocarditis, myocarditis, arthritis, and nephritis may occur as complications in this septic process.

Means of prevention of septic sore throat in epidemics must include a more frequent bacteriologic examination of the udders of cows and of the throats of those who handle raw milk. Pasteurization of milk would prevent these germs from causing infection.

The treatment of these septic sore throats is not different from that of follicular tonsillitis, namely, dilute hydrogen peroxid solutions 1 : 4, immediate subsequent washings with mild alkaline cleansing solutions, and the local application of a weak iodin solution, as Lugol's solution (too strong iodin preparations might increase the swelling and hyperemia of the throat).

On account of the prostration, the patient should receive plenty of nutriment. The bowels should be moved daily. Pain should be stopped, if it is troublesome, by codein or morphin, if deemed advisable. High temperature should be treated as seems best, and the complications combated as they occur. Infection of others is prevented by the same methods as those described for diphtheria. The blood in this disease should be studied, not only to determine the amount of leukocytosis, and the type that is probably present, but also to determine the amount that gives a favorable prognosis. Such studies may give a clue as to the possible value of an autogenous vaccine.

THE REDNESS OF CURED MEATS

The bright red which is exhibited by good meat is due in part to the oxyhemoglobin of the blood remaining in it, together with the comparable red pigment which is inherent in the muscle itself, even when it is completely freed from blood. A familiar effect of cooking meat is the pronounced change in color which it undergoes from the application of heat. The reddish tinge changes to a dull brown owing to the disintegration of the oxyhemoglobin, with the liberation of a protein component along with its color-producing group, hematin. A similar alteration is sometimes brought about when meats are cured with ordinary salt brine. Meats preserved in this way or by the application of heat alone, as in the canned meat industry, therefore assume an appearance quite unlike that of the flesh in its raw state.

On the other hand, it is a familiar fact that many meat products offered for sale, and likewise some of those prepared in the household, not only exhibit a bright red, but even retain this practically unchanged after cooking. Indeed, the color may even be intensified. This is true whenever potassium nitrate, or saltpeter, enters into the process. The redness of fresh meat is not destroyed after curing it by means of a mixture of common salt and a small proportion of saltpeter. This feature, in addition to the preservative action of the nitrate, is exhibited in the production of "corned" beef and other similar preparations. Canned corned beef is distinctly red.

The value of the long-practiced saltpeter process of curing meats is not confined to the meat-packing industries of commerce, but has long enjoyed a vogue in the household handling of flesh products that are to be kept some time before use. A recent summary of current knowledge regarding the coloring matter of raw and cooked salt meats by R. Hoagland[1] of the Bureau of Animal Industry in Washington makes it evident that the action of saltpeter in the curing process is primarily to cause the formation of the bright red and decidedly stable nitric oxid hemoglobin. The development of this compound is brought about by the presence of nitrates. The value of saltpeter as a flesh-color preservative is dependent on the reduction of the nitrate to nitrite.

Precisely as hematin, the color-yielding component of oxyhemoglobin, can readily be converted to a well-known reduction product, hemochromogen, so nitric oxid hemoglobin, the coloring matter of cured meats, can be changed under certain conditions to nitric oxid hemochromogen. The latter is commonly a result of the cooking process, and therefore represents the color of cooked salt meats. Hoagland states that it is very probable that in the case of meats which have been cured with saltpeter, or of meat food products in which saltpeter has been used in the process of manufacture, the reduction of nitric oxid hemoglobin to nitric oxid hemochromogen takes place to a greater or lesser degree, depending on conditions of manufacture and storage. The two compounds are so closely allied that their differentiation in one and the same product is not a matter of great importance.

Some idea of the extent to which the preserved color of flesh products is due to the factors noted above may be gathered from the fact that it has readily been recognized in such widely used meats as smoked pork and ham, cured pork, dried beef, corned beef, salami and cervelat sausages. Under the present laws it has been ruled that saltpeter may be used pending further investigation regarding its wholesomeness. The cause of the striking color of meats cured with it has been understood by few persons in the past. With a satisfactory explanation forthcoming, the medical profession is now in a position to know the facts and to be able to conjecture the preliminary treatment which meat retaining characteristic hues has received.

WINE OF CARDUI ACTIVITIES

Turning the light into the noisome pit of charlatanry always stirs into squirming activity those who subsist, either as hosts or parasites, on such business. For nostrum exploiters champion that comfortable doctrine, "Let Us Alone"; they inscribe as their heraldic motto: *Laissez-faire.* To the public unacquainted with THE JOURNAL's educational campaign of the past decade, it might appear that the exposure of the fraud connected with the exploitation of Wine of Cardui was a veritable crusade into a new field. During the past few months it has been necessary, almost daily, to assure interested laymen that the Wine of Cardui articles were but incidents in THE JOURNAL's general propaganda of education relative to medical frauds. The amount of "fuss and feathers" displayed in this specific case is due to several causes—remote and proximate. The most important, probably, is the fact that the chief owner of the Wine of Cardui business is one of the most prominent and powerful laymen in the Methodist Church. Of almost equal importance is the fact that the Wine of Cardui business has been, and still is, enormously profitable. Then there is the incidental fact that the growing spread of prohibition that threatens the millions invested in the distillation of alcohol makes the fate of "patent medicines" of the alcoholic-tonic type—a business not as yet legally affected by prohibitory laws—one of tender solicitude to the distillers. Add to these reasons the further one that the nostrum evil is, to-day, before the bar of public opinion, and it is easy to realize that the Wine of Cardui suits against the Americal Medical Association and the editor of The Journal are causing a stir such as inevitably follows the lavish expenditure of large sums of money.

---

[1] Hoagland, R.: Coloring Matter of Raw and Cooked Salted Meats, Jour. Agricultural Research, 1914, iii, 211.

An interesting story could be written of some curious coincidences that have occurred since the Chattanooga Medicine Company and its chief owner brought their suits. Articles appearing in the mouth-pieces of the "patent medicine" interests warning the public against the fell designs of the "Medical Trust" have been reprinted and widely circulated; nostrum-championing editorials of the "canned" variety have cropped out in those newspapers that may always be counted on to come to the defense of the "patent medicine" business; decoy letters have come to The Journal office from hypothetical "doctors," mailed from post-office addresses in villages in which the writers apparently rented a post-office box and to which they went in motor cars to get the "answers" that never came; detectives have posed as journalists seeking information about nostrums of the alcoholic-tonic type and have played the part of visitors to Chattanooga, solicitous (?) of the well-being of the new church organized after the split in the First Methodist Church of that city following the Wine of Cardui exposures; attempts have been made to "work" stenographers; efforts have been put forth to learn in advance the dates of public talks to be given on the nostrum evil under the auspices of The Journal—these are but a few of the many things that have occurred. Whether any of these occurrences bear any relation to the Wine of Cardui suits or are wholly or partly inspired by the general "patent medicine" interests, or whether they are simple coincidences, we leave for our readers to decide.

But to the medical profession the following synopsis of events will probably be of more interest than the trivial details of the "ways and means" of the nostrum business in defending its unwholesome brood:

1 *a:* The Journal publishes an article July 18, 1914, showing the fraud connected with the exploitation of Wine of Cardui.

b: Suit brought by the Chattanooga Medicine Company and J. A. Patten for $300,000.00 against the American Medical Association and the editor of The Journal.

c: The Journal publishes a second article Dec. 5, 1914, on the same subject.

2 *a:* Dr. Oscar Dowling, one of the trustees of the American Medical Association, in his capacity as President of the State Board of Health of Louisiana accompanies the State Health Train from New Orleans to Richmond, Va. The train carries among its health exhibits exposures of various nostrums including a card dealing with Wine of Cardui. A stop is made at Chattanooga.

b: Dr. Dowling is sued by the Chattanooga Medicine Company for $25,000.00, the papers being served on him before he left Chattanooga.

c: State Board of Health of Louisiana meets and upholds Dr. Dowling, and declares Wine of Cardui a fraud.[1]

3 *a:* The Limestone County (Ala.) Medical Society passes resolutions condemning the methods of the Chattanooga Medicine Company in soliciting physicians to testify for Wine of Cardui.

b: The Chattanooga Medicine Company sends legal representatives to Limestone County intimating that both the society and the individuals comprising it would be sued if the resolutions are not rescinded.

c: The Limestone County Medical Society "stands pat."

4 *a:* The Chicago City Club gives a Public Health Exhibition and among other exhibits has the American Medical Association educational posters on medical frauds, Wine of Cardui cards among them.

b: Local legal representative of Chattanooga Medicine Company attempts to bluff City Club into removing the Wine of Cardui posters.

c: Bluff "called." Nothing happens.

5 *a:* *Harper's Weekly,* in its series on fraudulent "patent medicines," gives some space to Wine of Cardui and its manufacturers.

b: *Harper's Weekly* sued for $200,000.00 by Chattanooga Medicine Company.

c: *Harper's* "comes back" in its issue of February 27.

SIDE-LIGHTS ON THE FUNCTION OF FERTILIZATION

It has long been customary to attempt the solution of some of the problems of protoplasm and the physiologic riddles of life by means of observations on lower organisms and simpler forms. The unicellular animals have afforded particularly useful and easily available objects for investigation from this point of view. Their supposedly simpler structure and more diffuse phenomena seem to render them particularly suitable to elucidate the more general properties of living matter. Among other questions, the problems of protoplasmic senescence and the significance of fertilization have seemed open to direct investigation in this field. In certain of the Infusoria, for example, reproduction proceeds by unprovoked cell division; but the frequent occurrence of conjugation, in all of the species, affords an instance of what may be looked on as the counterpart of fertilization in the higher forms.

---

[1] See Propaganda Department, page 761, this issue.

Is conjugation an indispensable activity for the prolonged generation of these lower organisms? A few decades ago it seemed established that continued reproduction by fission or division inevitably results sooner or later in degeneration and death. The evidence then available all pointed against the "potential immortality" of the unrejuvenated infusorian protoplasm and made it appear as if conjugation was the sine qua non for the life of the species. In other words, reproduction by division apparently could not proceed indefinitely without conjugation or some other artificial stimulus. The unique studies of Woodruff at Yale University have at length furnished a quite different answer to the rôle of such extrinsic stimulation in the life of the unicellular organisms. When subjected to suitable culture conditions, *Paramecium,* for example, has the power of unlimited reproduction by division without conjugation. This is attested by the fact that Woodruff has maintained a race of this infusorian in a normal condition over seven years through more than 4,500 generations without conjugation or the use of artificial stimuli. The essential condition for this success lies in the use of a suitable culture medium; if this environment is appropriate, the continued health and reproduction of the organisms results. There may be variations in the rate of reproduction by division without conjugation because of some unknown factor in cell phenomena; but recovery from declines thus resulting are autonomous.

Quite recently Woodruff and Erdmann[1] have discovered that despite the absence of conjugation or any form of artificial environmental stimulus, the "pure" races of *Paramecium* undergo remarkable rearrangements in the cells from time to time. It appears that the rhythms in the division rate are the physiologic expression of internal phenomena which involve the formation of a complete new nuclear apparatus, by a definite sequence of normal morphologic changes which simulate conjugation. This nuclear reorganization, in essence, consists of a gradual disintegration and absorption of the macronucleus in the cytoplasm. Simultaneously a multiplication of the micronuclei is in progress. Certain of the resulting micronuclei degenerate, while the remaining one or two form the new macronuclear and micronuclear apparatus. This results in the reorganization of the cell without the fusion of two animals.

This peculiar reorganization process, involving the intermingling of nuclear and cytoplasmic substances occurring within the cell, has been termed "endomixis." It is followed by a slight acceleration of cell phenomena, and a new rhythm is initiated. The process described places some of the fundamental questions of cellular physiology in a new light. We are wont to think of fertilization in the higher organisms as having both a dynamic and a hereditary rôle. If it shall appear that the cell has an internal regulatory phenomenon, endomixis, which is self-sufficient for the indefinite life of the unicellular races—that "senile degeneration" and "physiologic death" in the lower forms are not inevitable without conjugation—fertilization is emphasized anew as a process which attends to the transmission of new qualities. The fertilization mechanism is thus made primarily to serve functions of variation and hereditary transmission. In relation to the fertilization process in reproduction, therefore, the emphasis may be placed more strongly than ever on what it means for heredity rather than for rejuvenation.

Every contribution to the factors involved in the reproduction of cells is likely to throw some light not only on the normal growth of organs and the organism as a whole, but likewise on the pathologic development of tissues as they are exhibited in neoplasms. We need not disparage such studies because to the untutored "practical" mind the phenomena of the lowly creatures possessing a relatively simple organization have little obvious importance. On the contrary, it is a triumph of science to feel great hope that in the immediately near future a notable advance will be made in our grasp of what Sir Michael Foster called "the nature of that varying collection of molecular conditions, potencies and changes, slimy hitherto to the intellectual no less than to physical touch, which we are in the habit of denoting by the more or less magical word protoplasm."

REGENERATION OF FIBERS OF THE CENTRAL NERVOUS SYSTEM

Complete anatomic and functional regeneration of fibers in the peripheral nervous system has been demonstrated, but as regards fibers of the central nervous system, complete regeneration has been regarded as doubtful. From recent work, however, there is evidence that both in experiment and in pathologic conditions a marked attempt at regeneration of central fibers takes place. Without going into an extended consideration of the exact manner of regeneration of the fibers, a review of some of the work which has led many to believe this possible may be of interest. Perrero[1] regards the question of regeneration of fibers in the central nervous system as settled now that it is possible by efficient staining methods definitely to distinguish axis cylinders from glia fibrils. He examined

[1] Perrero: Contribution à l'étude de la régénération des fibres nerveuses du système nerveux central de l'homme, Arch. ital. de biol., 1910, liii, 21.

the cord of a man dying twenty-nine days after fracture of the fifth and sixth cervical vertebrae; there was complete softening of the cord in these segments, but immediately about the softened area, numerous changes were found in the pyramidal tracts above and in the posterior roots and columns just below the lesion. On the ends of many of the axis cylinders were cones and balls, a result of proliferation of the structures at the peripheral end of the nerve. Fine black threads were observed running out from several of these cones, and other axis cylinders were found broken up into fibrils. The black threads and fibrils displayed a tendency toward plexus formation about the blood vessels. Perrero regarded these as regenerative processes and found them present to an almost equal degree at each end of the injured cord. The regeneration was not extensive enough to pass through the softened area of the cord.

Rossi[2] after experimental hemisection of the cord found marked evidence of regeneration and new fiber production, though never of sufficient degree to pass through the cicatricial zone that forms between the two stumps. Here also regeneration was in equal degree in the central and peripheral stumps of the cord.

Bielschowsky[3] studied the changes in compression of the cord and in tumors of the brain and cord. He found numerous cones and button-like swellings of the ends of the axis cylinders. These were especially prominent about the blood vessels in the marginal zones of the cord around degenerated and compressed areas. He believes regeneration of the fibers in the central nervous system possible, and holds that two things are essential: one, good blood supply, the other, the presence of decomposition cells. These cells may be chemotactic; more probably they act as a framework or scaffolding along which nerve fibers develop. They then would play a rôle similar to the cells of the sheath of Schwann in peripheral nerve regeneration.

Marinesco and Minea[4] found that in experimental and pathologic conditions, regenerated fibers pass into the cicatrix from both the upper and the lower end of the cord. The new fibers end in cones and swellings, and these, they think, are derived from a dissociation of preexisting cylinders. The vessels are surrounded by a plexus of nerve fibers. These workers consider as all important the presence of *cellules atrophiques,* which have both chemotactic and nutritive influences on the new fibers.

Fickler[5] studied two examples of cord compression in which there was marked improvemet in the cord symptoms for some time before death. At the level of the compressed area there were no fibers in the cord. Above this level, however, were many newly formed fibers which passed into the anterior fissure of the cord and into the pia, and passing downward again, merged into the cord below the compressed area, thus connecting the pyramidal tracts above with the ganglion cells of the cord below. In the second example, newly formed sensory fibers passed upward by the compressed area of the cord in the posterior septum. Fickler concludes that fibers are capable of regeneration and that complete restoration of function is possible.

Thus the general view now is that blood vessels and a certain group of cells are especially important in regenerative efforts of central nerve fibers. Whether these cells, which have been called by various names, have a chemotactic or nutritive function, or act as a scaffolding, is still a matter of speculation. At any rate, attempts at regeneration are frequent and extensive, and in favorable instances, restoration really may be possible.

THE EFFECTS OF WEATHER ON PAIN, COMFORT AND EFFICIENCY

It is not at all uncommon to hear that a patient feels well or ill parallel to changes of the weather. There is no doubt that barometric and above all hygrometric changes produce distinct and often marked variations in sensation. Probably no information, however, is more fallacious than the vague general impressions with regard to these effects of the weather that are supposed to be common knowledge. For instance, it is a shock to most persons to learn that though dark, rainy days are supposed to produce depression, and bright, sunny weather to lift clouds of despondency, suicides are most frequent in June and least frequent in December. Cold weather is supposed to be a great source of suffering and consequent depression, especially to the working classes, and yet the cold winter months have fewest suicides and the warm summer weather the most. It is not the extremes of heat, however, which produce the despondency and ill feeling that lead up to suicide, for the climax of the curve of suicides is not reached in July or in August, when people have become run down from the persistence of hot weather, but in the pleasant month of June.

Evidently careful study is needed in order to determine the exact effect of weather on the disposition and the feelings. A careful analysis of suicide statistics was made by Dexter,[1] who analyzed 2,000 cases of suicide in one American city. When studied in connection with the weather tables, the fact was revealed that "the clear dry days exhibit the greatest number of suicides, and the wet, partly cloudy days the least;

[5] Fickler: Recherches expérimentelles sur l'anatomie de la dégénération traumatique et la régénération de la moelle épinère, Deutsch. Ztschr. f. Nervenheilk. 1905. xxix, 1.

[1] Dexter, Edwin: Suicide and the Weather, Pop. Sc. Month., April, 1901.

and with differences too great to be attributed to accident or chance. In fact, there are 31 per cent. more suicides on dry than on wet days, and 21 per cent. more on clear days than on days that are partly cloudy."

Dr. Ellsworth Huntington,[2] of the Department of Geography of Yale University, has called attention to the fact that there are some rather surprising results to be obtained from a study of efficiency in factories and in schools and colleges at different seasons of the year. The studies were made over a period of four years, and the plotted curves show that the lowest wages are earned during January; then there is a rather steady increase through February, March, April, May and the first half of June. During the latter part of June and through July and August, the curve remains at a lower level than in early June, but much higher than during the winter. About the end of August, people begin once more to work fast, and they go on at an increasing rate until the middle of November, when the rate begins to fall again. It recovers somewhat in December, owing evidently in part to the rush of holiday orders and in part to the extra incentive of the special need for money because of Christmas expenditures. Finally, at the end of that month, efficiency drops off rapidly to remain at its lowest all during January.

The chief differences between the curves for highest physical work and the maximum of mental effort, as illustrated by the class records of West Point and Annapolis, is that the fall maximum at West Point comes later than that of operatives and children, while the spring maximum comes earlier. At Annapolis the two maxima are pushed still closer together. "The two West Point maxima come more nearly in the winter than do the factory maxima, while the maxima at Annapolis are pushed still farther into the winter because the climate there is warmer than in Southern New York and Connecticut." The curves show that at very low temperatures, both mental and physical work are depressing. On days with higher temperatures, activity of both kinds increases, the increase being slight at first. Mental work reaches its highest point at a temperature of 38 F., while physical work reaches a maximum at 59 for men and 60 for girls. Above these temperatures for mental and physical work, the curves begin to fall.

There is a general impression that cold weather stimulates the circulation in human beings and arouses the activity of the nervous system, thus giving a greater capacity for work. This is true to a certain extent, but not for cold weather below the freezing point, in spite of persuasions to the contrary. The fall and the spring are the best working periods of the year for all kinds of work. A study of storms and their stimulating effect shows that change, especially rather sudden change of thermometric and barometric phenomena, are distinct stimulants. On the other hand, when the temperature remains more or less constant from day to day, people work and think more slowly.

As Dr. Huntington says, "We say bad things about our storms, we are loud in our defamation of the changeableness of the weather in the Eastern United States. In spite of this constant deprecation, every time that a storm passes over a region and is followed by cooler weather, peoples' efficiency is increased." We are inclined to think of an unvarying temperature as good for health and strength, but apparently it is not. Weather variations are distinctly good for us and for our efficiency.

Current Comment

THE BLOOD-SERUM IN ALKAPTONURIA

Alkaptonuria is the symptom of a perversion of metabolism whereby some of the aromatic fragments of the protein molecule, notably tyrosin and phenylalanin, are no longer converted into the usual end products of amino-acid disintegrative change in the organism. The tendency of the urine to become very dark when in contact with the air is due to the presence of homogentisic acid, a compound bearing a very close structural relation to the two amino-acids mentioned above. The rare anomaly of nutrition attended by the continued excretion of homogentisic acid raised the question as to its unique origin and real significance. At one time it was believed that the aromatic compound represented a product of intestinal putrefactive change and that it had its origin in the alimentary canal. To-day, however, this explanation of the genesis of homogentisic acid has been abandoned in favor of the well-established theory that it represents an actual abnormality in the intermediary metabolism of protein. The facts are that the administration of tyrosin or phenylalanin, or of proteins (which yield these amino-acids) causes a marked increase in the output of homogentisic acid in the urine of alkaptonuric persons. Even on a protein-free dietary the characteristic excretion may continue, though in diminished amounts, the tissue proteins evidently being the sources of the urinary substance. Normal persons, on the other hand, readily and completely destroy these amino-acids and the homogentisic acid. If we may look on the homogentisic acid in persons presenting these unusual conditions as the product of the incomplete destruction of some of the amino-acid structural units of the proteins, the question at once suggests itself whether or not homogentisic acid ordinarily arises in normal intermediary metabolism. If it does, then the essential difference between the normal and abnormal (or alkaptonuric) individual would be that the latter is unable to complete the metabolic destruction of certain aromatic amino-acids which the normal organism readily breaks down to the simplest final stages. The relation of the alkaptonuric to homogentisic acid or its precursors would thus present an analogy to the behavior of the diabetic toward sugar. Whether or not homogentisic acid really is an intermediary product in the normal metabolism of proteins and escapes detection because it is further decomposed as promptly as it arises cannot be definitely stated at present. There is some evidence that transitory alkaptonuria can be induced by excessive feeding of tyrosin.[1] If the hypothesis is tentatively adopted that homogentisic acid represents a normal stage in the metabolic disintegration, we at once become curious as to the place where it is normally broken down. Older experiments have shown that it can be made to disappear in its transit through the liver.[2] This by no means excludes the participation of other organs and of the blood itself. With respect to the latter fluid Oscar Gross of the medical clinic at Greifswald has furnished an interesting contribution.[3] Homogentisic acid is readily destroyed outside of the body by the blood-serum of normal persons. The serum of alkaptonurics, on the other hand, has no action whatever on it. Perhaps the key to the situation here and the explanation of the anomaly of alkaptonuria lies in the lack of an enzyme which ordinarily is present and competent to complete the metabolism of the intermediate product excreted in this unusual disease.

THE EMOTIONS AND ALIMENTATION

To experimental physiologists it is now a familiar fact that the peristaltic movements of the alimentary tract are easily inhibited by a variety of influences that may come into play in the every-day life of the human subject as well as the laboratory animal on which they have primarily been noted. The effect of the emotions on gastric peristalsis is not a new observation. Cannon, who has used the Roentgen ray, the most fruitful of all the technics applied in this field of study, long ago showed that rage, fright and anxiety abolish movements of the stomach. Other sensory stimuli bring about similar inhibitions of gastric peristalsis which can actually be observed in certain animals (rabbits) without any operative interference whatever, by mere inspection of the epigastrium as described by Auer.[4] The stoppage of intestinal peristalsis after similar inhibitory influences are brought to bear has been described for the human subject by various observers who used the Roentgen-ray method. If further evidence were needed to give emphasis to the profound dependence of the activity of the stomach, as regards both its secretory and motor functions, on the "condition" of the nervous system, additional proofs could easily be adduced. Quite recently a large number of facts have been gathered in the pharmacologic institute at Utrecht directly applicable to the question at issue.[5] They involve a careful record of the rate of discharge of bismuth meals from the stomachs of laboratory animals in various stages of psychic calmness or perturbation, but under otherwise comparable conditions. Without attempting to group the emotional states into well-defined categories, we may describe the subjects as ranging from individuals tame, unperturbed, readily amenable to handling and freely submissive to observation, on the one hand, to wild or frightened or refractory subjects at the other extreme. Corresponding with these emotional states the discharge of the meal from the stomach ranged in time from one and a half hours in the former group to three or even more hours in the case of the most unamenable subjects. Such figures are more expressive than a dozen sermons of the importance of a proper state of the nervous system in the normal performance of some of the functions of alimentation.

THE CULTIVATION OF TRYPANOSOMES

The development of suitable methods for the study of the growth of animal tissues outside of the body has encouraged much successful research in respect to the proliferation of various types of both normal and pathologic cells. It has made possible observations on developmental changes of such material as embryonic and tumor tissues and has pointed the way to the investigation of inhibitory as well as excitatory agencies. Fragments of neoplasms have been cultivated in glass apart from the organism which originally harbored them; and the mechanisms of their growth are thus being more clearly elucidated. By an adaptation of the devices used in this field, Dr. R. Erdmann[6] at Yale University has succeeded in following the development of certain important protozoa in a new way. Trypanosomes have, of course, been cultivated in the laboratory test tube in a variety of ways; but a satisfactory medium for culture on a slide has hitherto not been described. The value of such a scheme lies in the accuracy with which it enables the observer to study the sequence of changes in these microscopic organisms so as to reveal their true life history. By employing the plasma of the host as a culture medium either for the trypanosomes themselves or the growth in vitro of various infected tissues of the host, Dr. Erdmann has succeeded in keeping *Trypanosoma brucei* in normal condition for an indefinite period, whereas they die in a few days in other culture mediums. With the application of aseptic technic, the trypanosomes can be kept living, growing and dividing as they do in the host itself or in the transmitter. This promising method of investigating the complicated life cycles of protozoan forms which are parasitic alike in blood and in cells cannot fail to be an important contribution to the equipment for approaching the problems which they present.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

ARKANSAS

Tuberculosis Recommendations.—The board of trustees of the Arkansas Tuberculosis Sanatorium, Booneville, have recommended to the legislature, an appropriation of $100,000 for the next biennium. Of this sum $85,000 is desired for maintenance and $10,000 for the much-needed cold storage and power plant.——The board also recommends an appropriation of $50,000 by the legislature for the erection and maintenance of a sanatorium for negroes to be established near the center of negro population, either south or east of Little Rock. Of the desired appropriation, $30,000 is for the erection of the buildings and $20,000 for maintenance during the next two years.

CALIFORNIA

Medical Library Association Organized.—On February 4, physicians of San Diego met and organized the Medical Library Association. The following officers were elected: president, Dr. Fred. R. Burnham; vice-president, Dr. Harry C. Loos; secretary, Dr. Robert Pollock, and treasurer, Dr. Alfred D. Long.

Personal.—Dr. George E. Ebright, San Francisco, has been appointed president of the State Board of Health to succeed Dr. Martin Regensburger, term expired.——Dr. Benjamin F. Walker, Stockton, has returned after four months' service as surgeon in French field hospitals.——A banquet was given February 1, by the employees of the Health Department of Los Angeles in honor of the twentieth anniversary of the appointment of Dr. Luther M. Powers as health officer. Sixty employees of the department were present and a silver loving cup was given Dr. Powers by his fellow workers.——Dr. Harriett G. Probasco, Los Angeles, has been appointed physician at the Juvenile Hall.

ILLINOIS

Associate Staff Attendants Eliminated.—The efforts of the Chicago Medical Society to do away with the classification among the members of the attending staff of the Cook County Hospital have been successful. On February 19, the public service committee of the Cook County board adopted resolutions eliminating the classification of associate staff attendants.

Personal.—Dr. Henry B. Carriel, for fifteen years superintendent of the Jacksonville State Hospital, has resigned and Dr. Edward L. Hill, Red Bud, has been appointed.——Dr. Herbert H. Pillinger, Algonquin, who has been under treatment in a hospital in Elgin for an infected wound of the hand, has returned and resumed practice.——Dr. William A. Nason is reported to be ill at his home in Algonquin.

Hospital and Dispensary Notes.—The night warden of the Cook County Hospital announces that 100 beds are to be added to the tuberculosis ward at that institution.——Arrangements have been completed for the establishment of a free dispensary in connection with the Washington Street Commission, Springfield. Dr. Theodore J. Knudson, Springfield, is chairman of the special committee of the board.——Stakes for the administration building and eight other buildings of the State Epileptic Colony, Dixon, were set February 13.——The tuberculosis cottage and men's infirmary at the Watertown State Hospital are nearly completed. These two buildings and the nurses' dormitory are expected to be ready for occupancy early in the spring.

Report of the Edward Tuberculosis Sanatorium.—The annual report of Dr. Theodore B. Sachs, Chicago, medical director of the Edward Sanatorium at Naperville, shows that in 1914, 213 patients were admitted and 200 discharged, 186 of whom were classified as to results of the treatment. Of the total number of 186 cases the tuberculous process was arrested or "apparently" arrested in 62.3 per cent., became quiescent in 41.4 per cent., 20 per cent. were improved and 5.9 remained unimproved. During the eight years of the existence of the institution 1,162 patients were admitted and 1,073 discharged (a few were discharged a second time). Of these 103 stayed at the institution less than one month, while 91.4 per cent. of the patients remained an average of 19.2 weeks.

Chicago

Memorial to Head Nurse.—The alumni of St. Luke's Training School have launched the project of erecting a memorial training school and home to be known as the Margaret E. Johnstone Memorial, in memory of Miss Johnstone, for twelve years directress of the school, who died January 26.

Internists Organize.—The Chicago Society of Internal Medicine was recently organized with the following officers: president, Dr. James B. Herrick; vice-president, Dr. Robert B. Preble; secretary-treasurer, Dr. Charles A. Elliott, and executive committee, the president, secretary and Drs. Charles Spencer Williamson, Ernest E. Irons and Walter W. Hamburger.

Personal.—Dr. George G. Davis, who has been associate professor of surgery in the University of Manila, P. I., and assistant surgeon at the Mission Hospital, Canton, China, reached New York from England, February 15.——Dr. James H. Stowell has resigned as chief medical examiner of the North American Life Insurance Company, Chicago, and has been succeeded by Dr. Owen M. Knox.

Course in Surgery of the Natives of the Far and Farthest East.—A course of six lectures, illustrated, on so-called tropical surgery and borderline diseases, will be given at Rush Medical College during the spring quarter on Saturday afternoons at 3 o'clock, from April 3 to May 8, inclusive, by Dr. John R. McDill, Milwaukee, Wis., formerly professor of surgery, University of the Philippines, Manila. The lectures are free to the medical profession.

INDIANA

Good Work of School Nurses.—The work of three school nurses employed by the Indianapolis Board of Health, has given such good results that two more will be added. Since January 1 they have visited the homes of 1,279 children who have been excluded from school for various reasons.

Legislature Notes.—A bill compelling the attendance of the prosecutor at all insanity proceedings where the defendant has no representative, has been passed in the house of representatives. It is designed to prevent the railroading of people to the insane asylum.——The house of representatives has finally defeated the bill to establish a state board of chiropractic examiners. During the hard fight on this bill it was shown that during the last ten years only ten osteopathic physicians have been licensed in Indiana.

Open-Air Schools.—Reports on the open-air school for tuberculous children in Indianapolis have been so encouraging that the municipal school board has adopted a resolution that whenever the parents of forty children in two consecutive grades in any school district signify their wishes to have an open-air school started, the school board will provide the same.

KANSAS

Small-Pox Still Prevalent.—In Columbus over 100 cases of small-pox had been reported up to January 13. The mildness of the majority of cases makes the situation difficult to deal with, since many patients are not ill enough to recognize the need for medical treatment.

Districting of State.—A bill introduced in the house by Representative Bardwell provides for the apportionment of the state into thirty districts in proportion to population and assessed valuations, the organization in each district of a board of health and the appointment of a whole-time health officer.

Dispensary Opened.—The Associated Charities of Kansas City, Kan., have opened a free dispensary for the treatment of diseases of the eye, ear and throat, every afternoon from 12 to 2; for general medicine on Tuesday, Thursday and Saturday afternoons, and diseases of children on Monday, Wednesday and Friday afternoons.

Personal.—Dr. Walter S. Sutton, Rosedale, sailed for Europe, February 13, to take service in the hospital established by Mrs. Whitney.——Dr. Gilbert C. McCormick, Wichita, is serving with the American Ambulance in Paris.——Dr. Lucullus R. Sellers, Osawatomie, succeeded Dr. Benjamin F. Hawk, Harper, as superintendent of the Larned State Hospital.

KENTUCKY

State Health Board Officers.—At the January meeting of the State Board of Health held in Louisville, January 15, Dr.

W. Lucien Heizer, Bowling Green, was elected state registrar of vital statistics, and Dr. Lillian H. South, Bowling Green, was reelected state bacteriologist, each for a term of four years.

Measures Against Trachoma.—Provisional arrangements have been made for the treatment of cases of trachoma in Jefferson County (of which nearly one hundred have been found in the schools) in the local hospitals of Lexington.——A conference and course of instruction for the health officials, physicians and midwives of Lexington and Fayette County for the study of methods for the prevention and treatment of trachoma and ophthalmia neonatorum was held at the Phoenix Hotel, Lexington, Dec. 2, 1914.——Cases of trachoma were found in the schools of Versailles in a recent examination by Dr. John McMullen, Baltimore, of the Public Health Service. The children have been kept out of the school and treatment instituted.

Hospital Notes.—The new Bethany Hospital, located in the Combs Building, Winchester, was formally dedicated February 10.——A vigorous campaign is being waged to raise $50,000 for the erection of a hospital in Winchester.——The new Red Cross Sanatorium for Negroes, Louisville, was opened for public inspection, February 12.——The contracts for the children's pavilion to be connected with the Waverly Hill Tuberculosis Sanatorium, have been let. The contracts call for an expenditure of $12,000 and the building will be completed this summer.——Dr. Leon L. Solomon, dean of the staff of the Jewish Hospital, Louisville, has donated a department for clinical research to the institution. Dr. Leon K. Baldauf, Louisville, has been elected director of the new department.

Personal.—Dr. Dalferes P. Curry, St. Charles, has succeeded Dr. E. H. Mark, Bowling Green, as state sanitary engineer, with headquarters at Bowling Green.——Dr. J. F. Reynolds, Mt. Sterling, was thrown from his horse recently and suffered a comminuted fracture of the arm.——Dr. Delia Caldwell, Paducah, who has been seriously ill with pneumonia, is reported to be convalescent.——Dr. Fred. H. Johanboeke, Louisville, has been appointed state medical supervisor of Kentucky of the Royal Arcanum, succeeding Dr. E. R. Montgomery, Louisville, resigned.——Dr. T. M. Owen of the Federal Bureau of Animal Industry, who has had charge of the work for the eradication of foot-and-mouth disease with headquarters in Louisville, has been assigned to Norfolk, Va., where he will take charge of the work for the eradication of cattle-tick, in Virginia and North Carolina. He will be succeeded in Kentucky by Dr. A. J. Payne.——Dr. Jesse I. Whittenberg, Louisville, has been appointed county health officer of Jefferson County.

LOUISIANA

Clinic Building.—A clinic building is to be erected at a cost of $20,000 by the board of directors of the Presbyterian Hospital on a site acquired last year on Girod Street, New Orleans.

Tulane Medical Privileges Given to Women.—The board of administrators of Tulane University, at a recent meeting, adopted the recommendations of the medical faculty and granted all the privileges of the medical college to women students.

Tuberculosis Camp Deeds Delivered.—The deeds for 640 acres of land near Alexandria were delivered to Dr. Oscar Dowling, president of the State Board of Health, January 7. On this site, which is on a high bluff overlooking the Red River, the new State Tuberculosis Sanatorium, for which $10,000 has already been appropriated, will be erected.

Improvements in State Hospital.—Dr. Clarence Pierson, superintendent of the Louisiana Insane Asylum, Jackson, reports that during the year, $254,000 was spent in maintenance, new buildings and equipment. Five new buildings are in course of construction. During the year, 310 patients were admitted and the institution was administered at a cost per capita of 43 cents per day.

New District Society.—The Fifth District Medical Society was organized in Monroe, January 20, by Dr. Oswald W. Cosby, Monroe, and the following officers were elected: president, Dr. George W. Gaines, Tallulah; vice-presidents, Drs. Vern J. Funderburk, Monroe; Dix H. Alverson, Newellton, and William S. Rutledge, Ruston; and secretary-treasurer, Dr. James B. Vaughan, Collinston.

Personal.—Dr. Grover C. McKinney, Lake Charles, hookworm specialist of the State Board of Health, has been elected full-time physician of Calcasieu Parish.——Fire in Morgan City, January 20, destroyed the office and library of Dr. Charles C. deGravelles.——Dr. Sidney D. Porter, New Orleans, has been appointed secretary of the State Board of Health.——Dr. J. George Dempsey, New Orleans, has been elected president; Dr. George S. Brown, vice-president; Dr. G. Farrar Patton, secretary, and Dr. Everard W. Mahler, treasurer, all of New Orleans, of the Louisiana Antituberculosis League.

MARYLAND

Personal.—Dr. Karl Van Norden, formerly in the research department of Johns Hopkins Hospital and who has been an officer in the German army since the beginning of the war, was seriously wounded at the battle of Lodz but according to word just received has fully recovered and will return to the front at once.——Dr. Henry Deibel, Baltimore, was rendered unconscious in an automobile accident recently. His car was jolted from its course by running over a dog and crashed into a tree, throwing the doctor to the roadway. He is suffering severely from shock and bruises.——Dr. Arthur P. Herring, secretary of the state lunacy commission, has returned from South Carolina where he went at the request of the state authorities to investigate the conditions at the Columbia State Hospital.

Effect of Harrison Act.—The effect of the Harrison Drug Act, which becomes a law, March 1, is already being felt in the office of the supervisors of city charities, Baltimore. Many persons who will be unable to get narcotics from druggists and others, in anticipation of a rigid enforcement of the new law, have appealed to the supervisors for relief. Some pitiful cases have been recorded in the last few days. It is giving the supervisors considerable trouble to determine what to do with these persons, for none of the hospitals will take them. Those in charge at the Phipps Psychiatric Clinic have agreed to cooperate with the supervisors as far as possible. Those who cannot be treated at the clinic, will be sent back to the supervisors and it probably means that a ward at Bay View Asylum will have to be opened for such cases.

MINNESOTA

Hospital Addition Opened.—A four-story addition to the Swedish Hospital, Minneapolis, was formally opened February 9; the new addition will accommodate 52 patients.

Personal.—Dr. Howard Lankester, St. Paul, has recovered from his recent illness.——Dr. Frederick H. Buck, Shakopee, is reported to be seriously ill with scarlet fever.——Dr. R. L. Burns, Soudan, has completed negotiations to take over the Budd Hospital, Two Harbors.

Measles in the Agricultural School.—Under date of February 10, an epidemic of 28 cases of measles was reported among the students of the Agricultural School of the University of Minnesota, at Anthony Park. This epidemic again emphasizes the necessity of an isolation hospital on the university grounds and a special health officer for the university district, both of which have been asked for heretofore. Many of the students live outside the campus in private homes, and as hundreds of them were exposed to the contagion the possibilities of spread of the disease among the pupils of the city schools of Minneapolis and St. Paul are great.

Cost of Small-pox and Vaccination.—The State Board of Health reports that vaccination at public expense costs about 25 cents a person, while small-pox costs the public on an average about $50 per case. On this basis it is estimated that Minnesota's loss in 1913 and 1914 on account of small-pox was $233,000, or $100,000 more than the total health appropriation for the two years. Only about 1 per cent. of persons having small-pox in 1913 and 1914 had been successfully vaccinated within seven years; 6 per cent. had been vaccinated more than seven years previously. The disease in these persons was mild. All deaths and all severe cases occurred among the 93 per cent. of persons afflicted who had never been vaccinated.

NEBRASKA

Personal.—Dr. Marie H. Morse, Wisner, was seriously injured at Fremont, January 28.——Dr. Joseph S. Leisure, formerly of Clay Center, has been appointed a member of the staff of the Hastings State Hospital.——Dr. Tenny T. Harris has been reappointed chief of police surgeons of Omaha.——Dr. Porter F. Dodson, Wilber, was elected president of the board of secretaries of the State Board of Health, January 12.

NEW YORK

State Medical Society Meeting.—The one hundred and ninth annual meeting of the Medical Society of the State of New York will be held in Buffalo, April 27 to 29. The place of meeting will be the Sixty-Fifth Regiment Armory and on the last day of the meeting a regimental parade will be held, with review by Surgeon-General Gorgas, U. S. Army.

Superintendent of Supervisors Appointed.—Dr. Fred M. Meader, Syracuse, former city bacteriologist, has been appointed by State Health Commissioner Herman M. Biggs as superintendent of sanitary supervisors of the state. Dr. Meader will make regular visits to the various sanitary districts and will also be ready to answer emergency calls from any sanitary supervisor at any time.

Advise Closer Watch on Cattle.—The special commission, composed of Seth Low, Calvin J. Huson and Dr. Linsey R. Williams, deputy commissioner of health of the state of New York, appointed to investigate conditions among cattle, has submitted its report to Governor Whitman, in which it urges closer inspection of cattle, a general and frequent investigation of slaughter houses and the pasteurization of skimmed milk. The report holds that as many tuberculous cattle are slaughtered annually and made into sausage, which is liable to be eaten without cooking, farmers should be indemnified for cattle slaughtered by the state.

Ask Investigation of Private Institutions.—The legislative committee appointed two years ago to investigate the proposed taxation of Bloomingdale Insane Asylum in White Plains, has been submitted to the legislature. This report finds that the institution in question is conducted as a business proposition though some needy patients are treated free of charge, and it is on this latter fact that the institution has been free from taxation. The report recommends the appointment of a commission to investigate the feasibility of taxing all such institutions. It is estimated that the value of these institutions in the state is $10,000,000.

Hearing on Vaccination Bill.—February 10 a joint meeting of the House and Senate was held at Albany to hear arguments for and against the Jones-Tallett bill to limit compulsory vaccination of schoolchildren to communities in which epidemics exist. Among those heard were State Health Commissioner Hermann M. Biggs, New York, and Thomas E. Finnegan, deputy commissioner of education. Dr. Biggs is said to favor compulsory vaccination in first- and second-class cities, but not elsewhere. He thoroughly believes in the efficacy of vaccination. Dr. Finnegan said the present law requiring vaccination of all schoolchildren regardless of the presence of epidemics was difficult to enforce, and he favored the Jones-Tallett bill. Among those who spoke in favor of compulsory vaccination were Dr. Abraham Jacobi, New York City; Dr. Jay F. Schamberg, Philadelphia, and Dr. Franklin C. Gram, Buffalo. A number of laymen opposed compulsory vaccination unless it applied to all members of the community, or objected to it altogether.

Report on Feeble-Minded.—The State Commission to Investigate Provision for Mental Deficients, consisting of Robert W. Hebberd, secretary of the State Board of Charities; Dr. Max G. Schlapp, New York City, and others, which has been at work since last August, has submitted its report to the legislature. The findings are embodied in five conclusions with recommendations. These show the large number of defectives in the state, the lack of facilities for caring for them, the inadvisability of trying to deal with this class of individuals under the reformatory system, or in institutions for the insane, and set forth a plan for their care which seems somewhat ambitious. In the opinion of the committee, the problem is one which must be solved by the state, and the sooner such plans as suggested are carried out the more economical it will be for the state. It is especially urged that facilities for vocational training of the mentally defective pupils in the public schools should be greatly improved and extended and that there should be a better system of supervision than at present exists over the mentally deficient pupils.

Urge United States Control of Quarantine.—The Committee on Public Health of the New York Academy of Medicine has sent a letter to Governor Mitchell enclosing the report of its special study on the advantages that would accrue to the public generally and to this state in particular by placing the New York quarantine station under federal instead of state control. The report gives as reasons for urging this change: first, because of the international character of modern commerce the tendency of the last fifty years has been from provincial regulations to uniform national and international rules and laws; second, there are only two ports in the country whose quarantine stations are managed by local and state authorities; third, the United States, in order to be a responsible party to national agreement, must have control of all the ports of the country. The report further points out that as quarantine work is essentially scientific in its nature, it cannot be carried on efficiently unless the tenure of office is independent of changes in administration and politics. As the term of office of the present health officer expires this month, it is suggested that it would be an appropriate time for the government to transfer this work to the federal government. It is also shown that in 1913 and 1914 it cost $96,080 and $91,900, respectively, more to maintain the station than the revenue derived from it.

New York City

Personal.—Dr. Henry H. M. Lyle of St. Luke's Hospital sailed for France, February 10, to assume charge of the American Base Hospital, established and equipped by Mrs. Payne Whitney.

Money Saved by Health Department.—Dr. Sigismund S. Goldwater, health commissioner of New York City, has turned back to the municipal treasury more than $170,000 as the unexpended balance of its appropriation for the year.

Bar Dogs from Food Shops.—The Health Department has put into effect an ordinance forbidding the bringing of dogs into all stores where groceries, meat, fruit and other foods are displayed for sale. Signs directing attention to this ordinance have been displayed in all such shops.

Newspaper Attack on the Milk Commission and Dr. Park.—The New York *Globe* of February 11 contained an article by Alfred McCann, the exponent of the *Globe's* pure food campaign, describing the certified milk industry as conducted by the milk commission of the Medical Society of the County of New York and characterizing Dr. William H. Park as a "farce" and the cows "rotten." On the same evening at the meeting of the pediatric section of the New York Academy of Medicine, the chairman, Dr. Walter Lester Carr, spoke of the work of the milk commission which had been taken as a model after which milk campaigns for pure milk had been patterned in many cities all over the civilized world, and called on Dr. Park to explain the basis of Mr. McCann's amazing statements. Dr. Park stated that the accusations made against the veterinarian who had been making the test were absolutely false. Dr. Park said that as a matter of fact their tests have shown that 9 per cent. of all cows brought to the certified herds are tuberculous, whereas only 3 per cent. of cows in these regularly inspected herds have been found to be infected. Hitherto the tests have been continued over eighteen hours, but as a result of the facts they had gathered in regard to late reactions, such tests would hereafter be continued over twenty-four hours and would be made twice a year. Dr. Park stated that it had never been claimed that the certified milk was absolutely perfect, but they had used every precaution which was possible with the working force and funds at their command. It was also pointed out that with so large a proportion of the city milk supply pasteurized it was important to have a small supply of pure raw milk available. It was the general opinion that not only was the unwarranted attack on the work of the milk commission which has been purely philanthropic, to be deplored, but that the attempt to destroy public confidence in a work which has only the public welfare in view was most reprehensible.

OHIO

Sanatorium Capacity Increased.—The board of trustees of the Springfield Lake Sanatorium, recently opened by Stark, Portage, Columbiana, Mahoning and Summit counties, has added six beds to each of the public wards in the institution, thereby increasing the capacity from 72 to 96. There are at present 53 patients in the institution and 12 applications are on file.

Personal.—Dr. Ralph B. Thompson, National Military Home, was promoted February 20, and transferred to the Eddy Road Hospital, Cleveland.——Lieut. Earl B. Downer, M. C., Ohio N. G., Columbus, has been appointed staff surgeon for the American Red Cross and detailed to work in Servia.——Drs. Angus MacIver, Marysville, and J. Morton Howell, Dayton, have been appointed members of the State Board of Health.

Hospital for Criminal Insane Opened.—The Ohio State Hospital for the Criminal Insane, Lima, erected at a cost of

$2,000,000 was officially opened February 15. The superintendent, Dr. Charles H. Clark, estimates that about 600 patients will be housed in the new institution within the first four months. Dr. Clark is endeavoring to have the appropriation of $88,609.75 for the hospital the next four and one-half months, increased to the original estimate of $106,000.

Cincinnati

Personal.—Dr. Christian R. Holmes was reappointed a member of the board of hospital commission, January 26. Dr. Holmes returned from New York, February 12, after conferring with Eastern scientists regarding the new hospital.——Dr. H. Kennon Dunham has been reelected president of the Cincinnati Antituberculosis League.

Cincinnati General Hospital Opened.—On February 20 the new Cincinnati General Hospital, which took four years to build at a cost of approximately $4,000,000, was formally transferred by the commissioners who supervised its building to the municipal authorities. The formal act of transfer was completed when Dr. Christian R. Holmes, chairman of the commission, gave to the mayor two golden keys with which to unlock the doors of the various buildings. Addresses were made by Dr. Holmes, the mayor, Frederick Spiegel, and Dr. Henry S. Pritchett, president of the Carnegie Foundation for the Advancement of Teaching. Following the exercises a reception was held. In the evening a dinner was given by the chamber of commerce to the board of hospital commissioners, and this was a personal ovation to Dr. Holmes, who had done so much to make the building of the hospital a great success. Addresses were made by W. B. Melish, toastmaster, Henry S. Pritchett, Thomas C. Powell, Mayor Frederick Spiegel, Dr. Christian R. Holmes, Dr. Samuel J. Mixter of the Massachusetts General Hospital and Dr. Benjamin K. Rachford, resident of the hospital staff. Dr. Rachford paid a tribute to the medical profession of Cincinnati, which has upheld so splendidly the work of Dr. Holmes and his associates. Just before the close of the banquet, an announcement was made that may have a most important influence on the future of medical Cincinnati: Mr. Harry M. Levi stated that he will give $50,000 toward the establishment of a medical school in connection with the new hospital.

PENNSYLVANIA

Personal.—Dr. Lewis N. Reichard, Brownsville, who was operated on recently in Pittsburgh for appendicitis, has returned home.——Dr. Frank B. Witmer, Lebanon, was operated on at the Good Samaritan Hospital recently.——Dr. Thomas B. Hill, Waynesburg, was thrown from his horse, February 10, fracturing his clavicle.

Amendment Proposed to Anticigarette Law.—The act of 1913 provides a fine of not less than $100 and not more than $300. The amendment reduces the fine to not less than $5 and not more than $25, but the force of the new bill is that it will enable the crusaders to bring quick action against violators since it authorizes prosecution before any alderman, magistrate or justice of the peace. The Children's Aid Society, the Society for the Protection of Children from Cruelty, the Court Aid Society, and the officials and probation officers of the juvenile court are very much interested in the bill.

Osteopathic Standing Attacked.—The attorney general has received petitions to revoke the licenses of 161 osteopathic physicians practicing in various parts of the state and including that of O. J. Snyder, president of the State Board of Osteopathic Examiners. The reason given in the petition is "that the physicians are graduates of and hold diplomas from and degrees conferred by the Philadelphia College or Infirmary of Osteopathy, which institution, the petitioners aver, has never had the right to conduct such a college or to grant diplomas and confer degrees, and that therefore these physicians were never legally licensed, as applicants for license are required by the law to have a diploma from a legally incorporated college before they can be licensed to practice in this state." The petition relating to Snyder is based on the ground that the Northern Institute of Osteopathy of Minneapolis, from which he is alleged to have graduated in 1909, and "which it is also alleged has long since ceased to exist," was not a legally incorporated college within the meaning of the law.

Philadelphia

Med-Chi Alumni Meet.—At the annual meeting of the Medico-Chirurgical Alumni Association, the following officers were elected: president, Dr. Arthur C. Morgan; vice-presidents, Drs. Daniel J. Monihan, Chester; Frederick E. Ward, Easton, and Frank Sheppard; secretary, Dr. Erwin H. Erney, and treasurer, Dr. John A. Brophy.

Higher Entrance Requirements.—For the 1915-1916 term the Woman's Medical College of Pennsylvania, Philadelphia, asks the following requirements for admission: Candidates must have successfully completed work equivalent to that prescribed for the freshman and sophomore classes in recognized colleges. This must include collegiate courses in physics, general biology or zoology and chemistry (qualitative analysis is required; organic chemistry is recommended), together with appropriate laboratory exercises in each of these subjects, and two languages other than English (one of which must be French or German).

Medical Institutions About Philadelphia.—Mercy Hospital will shortly move to its new site on Twenty-Second Street below Reed. This hospital conducted for negroes by members of that race has been located on Fitzwater Street for the last eight years. A hospital building at 1413 and 1417 South Twenty-Second Street and a school for nurses is to include four stories, stone, brick and terra cotta, 32x110 feet, and to cost about $50,000, is provided in the architect plans. The new hospital will be a feeder for a convalescent sanatorium to be located just outside of the northwestern city limits.——The National Stomach Hospital, Fifteenth Street above Jefferson, an institution for the investigation and treatment of digestive disorders, was opened formally, February 9. The funds for the building of the hospital were subscribed by those interested in that branch of medicine.

SOUTH CAROLINA

Typhoid Prophylaxis.—The laboratory department of the State Board of Health, under the supervision of Dr. F. Asbury Coward, Columbia, prepared more than 40,000 doses of antityphoid serum during the past year, of which more than 39,000 were sent to physicians.

Personal.—Dr. James L. Napier, Blenheim, celebrated his seventieth birthday anniversary recently with an elaborate dinner to his professional confrères and friends.——Dr. Julius H. Taylor, Columbia, announces that henceforth he will devote his entire time to general surgery.

Hospital Notes.—The secretary of state has issued a commission to the Lee County Hospital Association at Bishopville, with a capital stock of $2,000.——The tuberculosis ward at the State Park Colony has been completed, and the administration building branch is almost ready for occupancy.

New Head of Government Pellagra Hospital.—P. A. Surgeon R. A. Herring, U. S. Public Health Service, who has been in charge of the government hospital for pellagra in Spartanburg since the opening of the hospital a year ago, has been transferred to New Orleans. P. A. Surgeon Randolph M. Grimm of the service has succeeded him. Dr. Grimm formerly spent considerable time in the study of pellagra in South Carolina, and was stationed for a time at Savannah, Ga.

Reorganization Approved.—As the result of the special investigation made by Dr. Arthur P. Herring, Baltimore, secretary of the State Lunacy Commission, dealing with the State Hospital for the Insane, Columbia, the following improvements in the institution are recommended: first, that the superintendent shall be appointed by the Board of Regents and not by the governor, and shall be removed only for cause and after hearing; second, that the Board of Regents shall consist of five members appointed by the governor with the sanction of the senate, shall be appointed for an ultimate term of six years and that they shall not be removed without cause and after hearing; third, that the superintendent shall make all appointments with the sanction of the Board of Regents and shall have power of administration subject to the approval of the board; fourth, that all regulations of the hospital shall be formulated by the board and executed by the superintendent and his assistants; fifth, that the name of the institution be changed from "State Hospital for the Insane" to "Columbia State Hospital"; and that the hospital for negroes shall be known as the "State Park Colony"; sixth, providing for voluntary dismissal; seventh, providing for a fiscal agent whose duty will be to see that patients who have relatives responsible for their support be made to reimburse the state; eighth, that no female patient be admitted to the hospital unless accompanied by a relative, a friend or nurse of the same sex; ninth, providing for a system of after-care of patients who are able to leave the institution although not fully recovered; and tenth, providing for the admittance, care and treatment of inebriates.——At a special meeting of the Medical Society of South Carolina, February 8, resolutions were adopted endorsing the efforts of Governor Manning toward improving conditions at the State Hospital and approving the proposed plans for reorganization.

SOUTH DAKOTA

Court Upholds Health Officer.—In a mandamus proceeding brought by a citizen of Sioux Falls against Dr. William F. Keller, city health officer, to compel him to provide accommodations for the treatment of a case of small-pox in a domestic servant other than in the home of the citizen, Judge J. W. Jones in the circuit court upheld the city health officer. It has been customary in Sioux Falls to remove patients with infectious diseases such as small-pox to tents in the summer, but in cold weather they have been treated in the houses in which the disease occurs. The city has no pest house or detention hospital.

WEST VIRGINIA

Personal.—Dr. Abraham S. Warder, Jr., Grafton, who has been confined to his home since Christmas as the result of a fall on the ice, is convalescent and has resumed practice.

Hospital Assured.—A ten-day campaign to raise $250,000 for the institution in behalf of the Ohio Valley General Hospital, Wheeling, has resulted in securing $254,493.31. The entire cost to the association of the subscription was little more than 2 per cent. The present debt of the association, including interest, is about $285,000, and it has an endowment fund of about $80,000.

WISCONSIN

Sanatorium Site Approved.—The Wisconsin State Board of Control has formally sanctioned the purchase of the Jeffrey Farm in Summer Township, as the site for the Kenosha County Tuberculosis Sanatorium.

Personal.—Dr. Edward J. Barrett, Sheboygan, has been elected a member of the executive committee of the Sheboygan Tuberculosis Society.——Health Commissioner George C. Ruhland, Milwaukee, who has been ill for several days, has recovered and resumed work.

Monthly Bulletin to be Issued.—A bulletin is to be issued monthly by the Milwaukee Health Department in place of the *Healthologist,* the publication of which has been discontinued. Much of the space of the bulletin is to be devoted to the explanation of new health measures, advice and to a crusade against quackery and nostrums. The official title of the publication will be *"Bulletin of the Health Department."*

CANADA

Meningitis Epidemic.—Cerebrospinal meningitis has broken out among the Second Canadian Overseas Contingent, located in Toronto. Six cases and one death have been reported.

Isolation Hospitals Planned.—The Windsor Board of Health has asked the city council to appropriate funds for the erection of three isolation hospitals, one in each ward of the city.

Barker the Guest of Honor.—At the thirty-third annual dinner of the faculty of medicine of McGill University held in Montreal, February 13, Dr. Lewellys Franklin Barker of Baltimore was the guest of honor.

University News.—In the officers' training corps of the University of Toronto, 1,800 men are enrolled. The medical faculty supplied 450; science, 500, and dentistry, 160.——The University of Alberta has been admitted to affiliation with the University of Oxford, England. A student who has completed his course in the former may study in the latter without further examination.

Personal.—Medical Health Officer Theophilus V. Hutchinson, London, Ont., has resigned and it is proposed to give him an honorarium equalling his salary for three years.——Dr. James Stowers, Montreal, has accepted a position with the American Red Cross unit at Paignton, England.——Dr. Keith Dean, Carlyle, Sask., sailed for England, February 7, for work with the expeditionary force.——Dr. James Roberts, medical health officer of Hamilton, has been ordered to report for duty with the stationary hospital number 2, Canadian expeditionary force.——Dr. W. D. Cowan has been elected president of St. John's Ambulance Association, Regina, Sask.——Dr. Henry R. Parent has been elected chairman of the Board of Health of Ottawa.——Dr. T. M. Flock has been appointed superintendent of the Tuberculosis Hospital, Essex County, Ont.——Dr. H. Eaglesham, Weyburn, Sask., has been elected president of the College of Physicians and Surgeons of that province.——Dr. Gordon Gray has been appointed senior demonstrator in physiology in the University of Alberta, and Dr. L. C. Coon, demonstrator in anatomy.——Dr. George H. Wilson, London, Ont., has been appointed medical officer of the Seventh Regiment Canadian mounted rifles.——Dr. George C. Hale, London, Ont., has been commissioned medical officer of the Eighteenth Battalion for overseas service, and Dr. A. V. Becher, London, medical officer Thirty-Third Battalion.

GENERAL

Harvard Graduate Surgeon-General of China.—Dr. S. H. Chuan, a graduate of Harvard Medical School, 1899, and a specialist on sanitary and preventive medicine, has been appointed surgeon-general of the Chinese army, and president of the Army Medical School, Tien-tsin.

Sociologic Congress.—The fourth session of the Southern Sociological Congress will be held in Houston, Texas, May 11. The general theme of the program will be the conservation of health and will be divided into the following six departments: (1) the prevention of communicable diseases; (2) moral health; (3) the health of children; (4) mental health; (5) health and race relations, and (6) the church as the conserver of social health.

Medical College Association Election.—At the twenty-fifth annual meeting of the Association of American Medical Colleges held in Chicago, February 17, Chicago was selected as the place of meeting for 1916, and the following officers were elected: president, Dr. Charles R. Bardeen, Madison, Wis.; vice-president, Dr. Reuben Peterson, Ann Arbor, Mich.; secretary-treasurer, Dr. Fred C. Zapffe, Chicago, and councilors, Drs. F. C. Waite, Cleveland, and Samuel W. Lambert, New York.

Bequests and Donations.—The following bequests and donations have recently been announced:

St. Luke's Hospital, New York City, $7,500 for the endowment of a bed in memory of his wife and two daughters, by the will of James C. Fargo.

Franklin Square Hospital, Boston; Free Hospital for Children, Brooklyn; Industrial School for Crippled and Deformed Children, Boston; and Boston Children's Hospital, equal parts of the estate of George N. Dana, after the death of the widow and certain legatees.

Boston Floating Hospital; Industrial Home for Crippled and Deformed Children, Boston; bequests by the will of Ellen Baird, Boston, after payment of certain specified bequests.

Methodist Episcopal Hospital, Indianapolis, the residue of estate appraised at $100,000 by the will of John Messick, Shelbyville, Ind.

National Health Week.—Booker T. Washington, president of the National Negro Business League, has issued from the Tuskegee Institute a call to the people of his race throughout the country to observe a national health week from March 21 to 27. It is further suggested that each community have a clean-up committee to investigate conditions which menace the health of communities. The call is addressed to daily and weekly newspapers, medical and other organizations and to state health officers. He calls attention to the fact that there are 450,000 negroes in the South alone who are seriously ill all the time, the annual cost of whose illness is at least $75,000,000. He says that 112,000 negro workers in the South are ill all the time and their annual loss in earnings amounts to $45,000,000, and that 225,000 die annually, 100,000 of which deaths could be prevented.

National Committee for Mental Hygiene Meets.—At the seventh annual meeting of this organization, held February 15, it was announced that Mrs. William K. Vanderbilt had contributed $44,500 and Mrs. Elizabeth Milbank Anderson $40,000, to be used in the extension of the work of the National Committee of Mental Hygiene. It was also announced that the services of Dr. Thomas W. Salmon, New York, had been contributed for a number of years by the Rockefeller Foundation. The organization proposes to extend its work by organizing state societies for mental hygiene throughout the country. Already seven states have such organizations and in twenty more groups of persons are preparing to establish them. As a part of the campaign of education a quarterly magazine containing articles on mental hygiene, the prevention of insanity and the care and treatment of the insane, the feeble minded and alcohol and drug victims will be published. The following officers were elected for the ensuing year: president, Dr. Lewellys F. Barker, Baltimore; vice-presidents, Dr. Charles W. Eliot, Boston, and Dr. William H. Welch, Baltimore; treasurer, Otto T. Bannard; medical director, Dr. Thomas W. Salmon, New York, and secretary, Clifford W. Beers.

FOREIGN

Suspension of Italian Periodical.—The *Gazzetta Medica Italiana*, founded and edited by Prof. Senator Carlo Forlanini, has ceased publication.

Memorial to Miraglia.—A memorial tablet has been placed on the house at Cosenza, Italy, where the eminent alienist, B. Miraglia, was born, and a similar tablet is to be placed in the insane asylum at Aversa, the scene of his work, and a street in Aversa is to be named after him.

Italy Places More Restrictions on the Liquor Trade.—Last month the new regulations went into force in Italy prohibiting the sale of liquor, even wine or beer (except at meals), to minors under 16, to drunken persons, to feeble persons and to those with mental derangement. The sale of liquor is also strictly prohibited on holidays and election days. Stringent regulations in regard to licensing of saloons also come into force, and the sale, manufacture or importation of absinthe is absolutely forbidden.

Deaths in Profession Abroad.—L. Loewe, a specialist at Berlin in diseases of the ear, nose and throat, and author of several large works on these subjects, aged 71.——M. Höfler, a leading balneologist and student of medical history, especially folklore and medical nomenclature, recently succumbed at Tölz in Bavaria to cancer of the liver, aged 66.——H. Schiess-Gemuseus, long professor of ophthalmology at the University of Basel, where he organized the first eye clinic and wrote many articles on the eye for various scientific periodicals, died recently, aged 82. He retired from his chair at the age of 60, and ten years later lost the sight of one eye from detachment of the retina, soon followed by total blindness from a cataract of the other eye.——L. Pastro of Venice, senator of the realm, died January 22, at an advanced age.——A. Marcacci, professor of physiology at the University of Pavia, author of numerous works on physiology.——The names and addresses of eight physicians who lost their lives in the recent earthquake in Italy, are given in the latest *Policlinico.*

WAR NOTES

Personal.—Dr. Charles S. Pancoast, Camden, N. J., is now connected with the American Red Cross Hospital unit at Budapest, Hungary.——Dr. McDonald, chief surgeon of the American Red Cross Hospital at Budapest, with Surgeons Jewitt and Miller and one nurse connected with the staff, has had conferred on him by the Archduke Francis of Austria the Red Cross badge of honor, second class.

Auto Ambulance Service.—The American Ambulance Hospital, in Paris, has now nearly ninety ambulances in service, most of them at the front. The statistics show that the mortality in the American Hospital has been less than 8 per cent, and that up to January 31, the hospital had received $440,000, of which $120,000 was contributed by Americans in Europe. There are at present 398 patients in the hospital, and the average cost per patient per day is $1.50. The cost of the maintenance of an ambulance is about $200 a month.

Transfer of Wounded in France.—Twenty-seven ambulance trains are in operation in the north of France, but the evacuation of the wounded is much hampered on account of the troop and ammunition trains which are given the right of way. It is reported that 36,000 wounded have passed through Limoges, and that in one night 800 wounded arrived and that there were only three ambulances to handle them, and that the blanket supply was exhausted. At Havre, 4,000 wounded were expected, and 8,000 arrived, in addition to many German prisoners.

More Nurses for War Work.—Ten additional Red Cross nurses sailed for France on the *Rochambeau,* February 20. Of these, nine are to be sent to Yvetot, and one, the head nurse of the department of surgery of the Rockefeller Institution for Medical Research, goes to Paris to assist Dr. Alexis Carrel, who has been detached from the Lyons Hospital and has been assigned to the hospital at Compiegne near the northern battle line. This hospital will accommodate about 100 patients, and is being equipped by the Rockefeller Institute with complete apparatus for research in bacteriologic, pathologic and chemical and surgical conditions which may arise, with especial reference to the study of infected wounds.

Good Work of the Servian Red Cross Unit.—Dr. Edward W. Ryan, surgeon-director of the American Red Cross unit, located at Belgrade, reports that at the time of the Austrian occupancy of Belgrade he was left in charge of all the hospitals in the city. At one time he and his assistants had 3,000 patients in their care with frozen hands and feet. A large number of these wounded had had not even first dressings and many of the wounds were infected. Under Dr. Ryan's charge were five hospitals with about forty buildings, nine Servian physicians, 150 nurses and about 1,200 patients and also the insane hospital and civil, surgical and medical hospitals. In addition to this, Dr. Ryan had to provide food for about 6,000 poor. Before the Servians retook Belgrade 6,000 wounded passed through the hands of the Red Cross Hospital, and as it was impossible to handle these cases, they were sent into the interior of Hungary with the exception of about 750, who were retained in Belgrade.

Aid for Belgian Physicians.—The report of the treasurer of the committee of American physicians for the aid of the Belgian profession, for the week ended Feb. 20, 1915, shows the following contributions:

Dr. Sylvester J. McNamara, Brooklyn, N. Y.	$	5.00
Dr. Junsai Watanabe, Seattle, Wash.		5.00
Anonymous — B., Pittsburgh, Pa.		30.00
The Erie County Medical Society, Erie, Pa.		25.00
Dr. Hugh Cabot, Boston, Mass.		25.00
Dr. Edward Evans, LaCrosse, Wis.		10.00
Dr. Willet J. Herrington, Bad Axe, Mich.		10.00
Otero County Medical Society, La Junta, Colo.		25.00
Vermillion County Medical Society, Danville, Ill.		25.00
Dr. Eva Charlotte Reid, Talmage, San Francisco, Cal.		5.00
Dr. Howard Carter, Webster Groves, Mo.		5.00
Dr. George H. Torney, Brookline, Mass.		5.00
Dr. John B. Murphy, Chicago, Ill.		100.00
Dr. Donald E. McGillivray, Port Angeles, Wash.		5.00
Dr. Charles N. Spratt, Minneapolis, Minn.		100.00
Dr. John M. Thorne, Pittsburgh, Pa.		5.00
Westerly Physicians' Association, Westerly, R. I.		10.00
Dr. J. P. Long, Astoria, Chicago, Ill.		1.00
Dr. Roy Sexton, Streator, Ill.		5.00
Dr. Delos E. Cornwall, St. Maries, Idaho		5.00
Aesculapian Club of Buffalo, Buffalo, N. Y.		25.00
Pocatello Medical Society, Pocatello, Idaho		10.00
Dr. Arthur R. Thomas, West Eaton, N. Y.		5.00
Receipts for week ending Feb. 20		$ 446.00
Previously reported receipts		$3,133.00
Total receipts		$3,579.00
Previously reported disbursements	$3,135.00	
Disbursements week ending Feb. 20, 200 boxes food at $2.20 per box	$ 440.00	
Total disbursements	$3,575.00	3,575.00
Balance	$	4.00

F. F. Simpson, M.D., Treasurer,
5 Jenkins Arcade Building, Pittsburgh, Pa.

LONDON LETTER

London, Feb. 5, 1915.

The War

GIFTS OF CLOTHES FOR THE SOLDIERS

A needlework guild, founded by the queen on the outbreak of the war, has sent to the front an enormous amount of warm clothing in the form of knitted garments. Just before Christmas there was a special collection of knitted woolen socks and belts to the number of 970,000 from all parts of the empire, from every continent, from the United States, and from every country where English is spoken gifts of clothes have been sent. In five months no fewer than 789,562 garments have been received.

BOULOGNE UNDER THE RED CROSS

The French seaport and watering place has undergone an extraordinary transformation. It is now what may be termed a hospital town for the British wounded. All the principal hotels are turned into hospitals or lodge the officials of the British Red Cross Society. At the railway station the goods sheds have been converted into an enormous military hospital. The work has been so well done that dismal uninhabitable buildings have been changed into a series of spotlessly clean, bright wards, well lighted, warm and ventilated. There is even a specially equipped ward for pneumonia cases, and two thoroughly up-to-date operating theaters. The Casino has also been converted into a hospital. The Café restaurant makes a fine ward, containing over ninety beds, and at the "bar" medicines are now dispensed. The finest ward of all is the great Baccarat Hall. The cashier's office is now a sisters' room, and the "American bar" a Roentgen-ray room. Never have the British wounded, or probably any wounded, been so well looked after. The hospitals are as well staffed as they are equipped. Eminent consulting physicians attached to the army visit daily to advise on medical cases of difficulty, and a still greater number of eminent surgeons attend, and no major operation is performed without the approval of one of them. There are also specialists as well as operating surgeons who are celebrated for particular work. The transport is equally good. The Red Cross Society has some nine hundred motor ambulances on the roads of France. They are at every point of the lines of communication and at every base, and are ready at any hour of the day or night. There is also now an adequate number of ambulance trains on the lines of communication, and the latter types embody the newest refinements in hospital-train construction.

GERMAN PRISONERS IN ENGLAND

A Danish gentleman, Mr. A. Goudsmit, has visited four of the German camps for prisoners in England and reports that the treatment of the prisoners is "splendid." The officers in charge do their best to make the lot of the prisoners as tolerable as possible. The food is excellent and arrangements are made for the men to have regular exercise. Mr. Goudsmit is about to return to Germany with the object of procuring the release of every British non-combatant and the exchange of crippled military prisoners. The British government has now completed, for the internment of some two or three hundred German officers, Donington Park, Leicestershire, the property of Mr. Frederick Gretton. They have spent $100,000 in adapting the place for the purpose. The well-wooded park comprises about 400 acres, but only 20 acres immediately adjoining the hall will be used by the prisoners, this space being enclosed by barbed-wire entanglements, 8 feet high, 6 feet wide, and let into the ground to a distance of 3 feet. Additional dormitories built of wood have had to be erected a few yards from the hall, for some of the prisoners and for the guard.

THE MANUFACTURE OF SYNTHETIC DRUGS

Before the war we were almost entirely dependent on Germany for synthetic drugs and the stocks in this country were not sufficient. Consequently, these drugs have become scarce and expensive. Progress, however, has been made in their manufacture. A license to manufacture salvarsan has been obtained by one firm. At the request of the admiralty, the organic chemistry department of the Imperial College of Science and Technology has been conducting experiments since September, under the direction of Prof. J. F. Thorpe. The admiralty asked the Imperial College to prepare for them 30 pounds of phenacetin, 50 pounds of hexamethylenetetramin and 1½ pounds of beta-eucain. The required quantities have now been forwarded to the naval hospitals.

Epidemic of Influenza in London

Since the outbreak of the war the public health has been remarkably good, but the record is now being threatened in the case of London, at any rate, by an epidemic of influenza. This epidemic has taken a more modified form than in recent outbreaks, and the gastric symptoms which were a distinguishing mark of last year's visitation are absent. On the other hand, the present attack is most infectious, and whenever it has seized on an individual it has usually run through the household of which he is a member. Whole offices have gradually succumbed, and as the mildness of the attack lures the sufferer to continue his normal occupation, the disease has a full opportunity of extending. A large number of cases have taken the form of pleuropneumonia, but when the complaint has not developed so gravely the symptoms are chiefly headache and a transient feverish condition, combined with tonsillitis.

Perjury in a Libel Action Against the British Medical Association

In my letter published in The Journal, September 12, last, I reported the second libel action brought against the British Medical Association by a man named Stevens, the proprietor of a quack medicine. He professed to cure consumption, and was exposed in the association's book, "Secret Remedies." In the first action the jury disagreed, and in the second gave a verdict in favor of the association. That such a powerful body as the association should have difficulty in avoiding being mulcted for damages by a notorious quack is remarkable, but the following throws some light on the matter. In my previous letter I said that a physician gave evidence on behalf of Stevens, and stated that he had practiced in West Africa and had heard the name "umckaloabo" (the alleged plant used by Stevens in preparing his remedy). It was a Kafir word, he said, meaning "life everlasting," and was valuable in chest complaints. He professed to be a ship's doctor, and also produced a paper to show that he had some sort of commission from the government of Liberia. It has now been ascertained that this person has no medical qualification. For a time he was connected with a training enterprise in Liberia, and for a short time had a sort of surgery there. He has been arrested on the charge of perjury.

PARIS LETTER

Paris, Feb. 4, 1915.

The War

THE EMPLOYMENT OF SURGEONS AND PHYSICIANS ACCORDING TO THEIR ABILITIES

Among the criticisms which have been addressed to the military health service there is one which bears on what has been called the non-utilization of abilities. Thus well-known military surgeons have been confined to administrative functions, etc. The Societé médicale des hôpitaux de Paris has recently taken up this question, and after a report made by a committee composed of Drs. Gilbert Ballet, Mathieu and Netter, unanimously passed a resolution which has been presented to the minister of war demanding that the military health service take account as far as possible of the personal aptitudes, not only of surgeons, but also of the physicians serving with the army, and that the physicians of the hospitals of Paris and of the other important cities should be so placed in the medical services that it may be possible to utilize their knowledge and experience to the best advantage of the patients. The society hopes also that the sick and wounded may, in future, be able to benefit more largely than in the past by the care of qualified specialists in neurology, psychiatry, ophthalmology, otology and stomatology.

TREATMENT OF WOUNDS OF WAR

I mentioned in a previous letter (The Journal, Sept. 19, 1914, p. 1043) a paper read before the Académie des sciences last August by Dr. Delorme, medical inspector general of the military health service, entitled "Advice to Surgeons." According to Delorme, in the great majority of cases it is unnecessary to operate; even wounds of the abdomen follow a very simple course. In cases of fracture, he believes, it is unnecessary to remove fragments, whether adherent or free; the search for foreign bodies and their extraction is useless.

Dr. Hartmann, professor of clinical surgery at the Faculté de médecine de Paris, has just published in the *Revue Scientifique* an article showing, on the basis of the experience of four months of war, how erroneous this advice is. Delorme, in his advice to surgeons, takes into account only bullet wounds. In the present war, we are confronted very frequently with wounds made by artillery projectiles, fragments of shell or shrapnel (two wounds by artillery projectiles for every one by bullet) and, still oftener, by infectious complications, so that it is quite necessary to remove foreign bodies and fragments of bone and to open and drain the wounds. To preserve limbs, active treatment is necessary; to confine oneself to a policy of abstention, applying merely an aseptic or antiseptic dressing, is to risk the loss if not of the patient's life, at least of his limb. Wounds of the abdomen are far from presenting the benignity attributed to them by certain military physicians. What ought to be understood is the frequency of infections and suppurations. In wounds made by bullets which have struck the parts directly and have not, in their course through the tissues, met anything hard, the course of the case may be simple, and here it is appropriate to refrain from exploration of the wound and the search for foreign bodies. The simplest dressing, provided it be surgically clean, is sufficient for cure. Unfortunately, such cases are in the minority.

A bullet wound which is extremely small, almost closed, at the orifice of entry, may present, if the ball has struck bone, an enormous wound with great laceration of the parts at the orifice of exit, so that the wounded are constantly inclined to talk of explosive or dumdum bullets. This great difference between the wounds of entry and of exit is extremely striking in cases of transfixing wounds of the hand. The ball is rendered "explosive" by the mere encounter with the bones of the wrist. The same thing is true of bullets which have ricochetted and have become deformed. Bullet wounds, then, are far from having uniformly the benignity which has been attributed to them.

As for wounds made by fragments of shell or shrapnel, it is rare that they do not produce suppuration. Even in some cases in which the entrance wounds seemed aseptic, Hartmann has found, after the extraction of the shrapnel, a little collection of pus at its former site. Any one who believes that to-day the use of tincture of iodin and aseptic dressings has abolished suppuration in wounds of war, is greatly deceived. Such wounds, fortunately, generally disinfect themselves quite rapidly. A patient may arrive with a high temperature and a huge sanious wound, sometimes even putrid or covered with gangrenous exudate; yet in a few days the fever falls, the wounds rid themselves of infection, and the course runs rapidly toward cure. This is an observation frequently made in cases of wounds which are chiefly open and involve only the soft parts.

Whatever may be the complexity of the lesions, unless there is gangrene of the limb (which is exceptional), Hartmann has always practiced conservation; he has never amputated. Astonishment has been expressed at the way in which cure occurs of apparently dangerous lesions. This does not mean, however, that all operative intervention should be eschewed. On the contrary, infected wounds should be freely opened up and foreign bodies and movable fragments of bone removed. In no cases have complications, outside of some secondary hemorrhages, been observed to follow such operations.

As for dressings, aside from the rare cases of uninfected bullet wounds, for which a drop of tincture of iodin and an aseptic dressing are sufficient, Hartmann has always sought to open up the wounds freely and has irrigated them with hydrogen peroxid or phenol solution, even bathing the part with the antiseptic or, when the region is not suitable for such treatment, using an antiseptic spray with the Lucas-Championnière atomizer. In cases of ill-smelling, sanious or gangrenous wounds, compresses wet with a dilution of Javelle water constitute a simple and inexpensive dressing which seems to Hartmann superior to tincture of iodin.

BERLIN LETTER

Berlin, Jan. 26, 1915.

The War

FOOD SUPPLY

The possibility of the cutting off of our supply of foodstuffs has been the occasion for our limiting the employment of what is left of our food supply. It has been shown by noted physicians like Rubner, as well as by experts in political economy, that our supplies are sufficient, not only to save us from starvation, but also from any condition of undernutrition. We must take into account, however, the possibility that the next harvest may be less abundant than we suppose, and as there is nothing to indicate how long the war will last, the government has deemed itself compelled to force the population to economy by means of regulations. Naturally, the number of those who are intelligent enough to practice moderation spontaneously is not particularly larger than usual, but after it was determined that the regulation for the economic use of meat and particularly of the breadstuffs were not sufficiently observed either by the dealers or consumers, the government has now published provisions which will exert an extensive compulsion on both parties. After February 1, all the supplies of wheat and rye, as well as of wheat, rye, oat and barley flour (with the exception of very small quantities) are to be confiscated. The distribution of all these supplies to the individual communities is undertaken by an imperial distributing station which will be constituted by representatives of the imperial government and of the communal and some commercial associations. To this imperial distributing station, which is located in Berlin, the communal associations must apply for the necessary supplement of their grain and flour supplies as well as to give up any excess that they may have to the needy communities. The communal societies and the communities charged with the distribution of the flour supply must take care that there is a uniform satisfaction of the need of bread for all classes of the community. The way in which this is to be accomplished is left to their discretion. In the case of necessity, the communities may adopt extensive regulations for the use and sale of flour and bakery goods. They may order that only bread of a single form may be prepared, they may forbid or limit the trade in cakes and the distribution and receipt of bread and flour to definite quantities and limit the places where it may be distributed and the time. In addition, it may, for instance, be prescribed that bread may be furnished only on the presentation of a ticket sanctioned by the police in the amount designated as permissible and at a definite time. Finally, dealers, bakers and confectioners can be forbidden to supply bread and flour outside of the neighborhood of their business location. The regulation of the government to secure a supply of meat provides that all communities with more than 5,000 inhabitants, in order to furnish the population with meat, must keep on hand a supply of staple goods (pickled meat, smoked goods, bacon and sausages) and must take care for their preservation. The sale is then regulated by the community.

WAR AND RACIAL DEVELOPMENT

In consideration of the enormous extent of the war and the enormous number of soldiers that each nation is putting into the field, the question arises as to what will be the future of the nations involved in the war in sanitary respects if the war destroys such a large number of the most powerful and best developed men, but spares those less capable, the abnormal and diseased who cannot go into the army. This question is answered in an article by the Bonn pathologist, Prof. Hugo Ribbert. He considers the most extreme case, but one which would never be realized, that is, that no one would return from the army. Then for a number of years the nation would lack the men without whom it could not maintain its highest efficiency. To be sure, those who were excluded from the army, by increased exertion, could accomplish a part of that which those who were lacking might have produced, but there would be a certain falling off in the average of accomplishment. On the other hand, however, those who did not take part in the war, with reference to their racial characteristics, and that is the important thing, are not unconditionally of less value, as the diseases which are important in producing unfitness for service have nothing to do with racial characteristics. Another danger is much more serious; that is, the race will be propagated exclusively by the unfit and, to a certain extent, by diseased persons. The percentage of defective and diseased progeny would be so much larger than usual, in proportion as the fathers were not fit for breeding or as the children were exposed to the danger of an infection, particularly to tuberculosis, and because the hereditary pathologic conditions would be transmitted to the children. This danger would be mitigated, however, by the fact that among those unfit for service, there are many who cannot participate in the war for unimportant reasons that scarcely affect their own existence or that of the people, or whose defects cannot be transmitted to their children. Further, not all the progeny are tainted with a hereditary disease because, according to the mendelian laws of heredity, a part remains free, and, moreover, those fit for the war would have begotten a certain number of diseased or abnormal children had they remained at home, and this number must be subtracted if one wishes to determine the effect of the war on the development of the race. On the other hand, it must be remembered that if the hereditarily tainted progeny marry with each other, men and women with the same hereditary characteristics will mate more frequently than before the war. Consequently, the probability of a progeny with the same hereditary taint will be increased, but this danger is not to be rated too high, for the progeny of the unfit is not evident for all succeeding generations. Many with hereditary taint and particularly with the most serious defects do not marry. They would appear quite as rarely as they have in the course of centuries in mankind in general, for, so far as one can judge, the number of individuals with hereditary disease has only increased in the same proportion as the total of the human race. If, in spite of this, a degeneration of the human race is asserted, it must be assumed that certain external injurious circumstances have had, as a result, the appearance of new hereditary diseases.

Now, the assumption that none of those taking part in the war will return is, of course, to be rejected. If only 10 per cent. die, the results that have been mentioned would be so slight that they would scarcely exert any influence in the next generation. The results would be more serious without any extreme assumption if the war should last several decades, like the campaigns of Napoleon, which entailed the slow deterioration of the French nation by the extensive extinction of vigorous individuals.

We may hope that we will be spared such serious disadvantages from the war. It will indeed require a sacrifice of human life which will hinder the development of the people and only be compensated for in a long time, but it will not last so long that this loss will be too striking. The majority of completely efficient men will return and, for that reason, it is not to be feared that the disadvantageous influence of the unfit on the next generation will be very great. The number of efficient men will be quite large enough to insure the vigor of the next generation. This expectation should inspire us with the greatest care to take measures for racial hygiene; that persons with especially severe hereditary taint shall not be allowed to marry, and that no new transmissible defects shall be added to those already in existence.

Association News

THE SAN FRANCISCO SESSION

Ample Hotel Accommodations in San Francisco Assured by Large Number of Rooms Available

117,232 rooms in San Francisco hotels and apartment houses, 56,578 of which are in hotels of 50 rooms and over, are available for use by those attending the 1915 session, according to the announcement of the subcommittee on hotels. As was stated in The Journal last week, this committee has the cooperation of the San Francisco Hotel Bureau, a corporation formed to make as easy as possible the securing of the particular kind of accommodations wanted and at guaranteed rates. This Bureau is incorporated with a capital of $100,000, and is conducted with the official endorsement of the Panama-Pacific International Exposition, San Francisco Convention League, the San Francisco Hotel Association, and other civic bodies. With the cooperation of this responsible Bureau, the subcommittee on hotels assures Fellows of the Association and their guests that the hotel rates will be reasonable. The hotels represented by the Bureau announce a general tariff of from $1 to $3 a person, per day, European plan; and from $3.50 and up, a person, per day, American plan. While, in a few of the more fashionable hotels, the rates are from $4 to $10 a person per day, all who attend the session can be accommodated with modern and good quarters at the lesser rates. Contracts will be made at these rates for any date and for any length of time desired. The most direct way to obtain information regarding the particular kind of hotels or rooming house accommodations desired, is to indicate on the application blank which appeared on page 21 of the advertising section of last week's issue of The Journal (Feb. 20, 1915) (1) whether a hotel or apartment house is desired; (2) if a hotel, whether European or American plan; (3) state definitely the date on which you expect to reach San Francisco; (4) the probable length of your stay; (5) the number of persons to be accommodated, and (6) maximum rate that will be paid. On receipt of your request, the Bureau will furnish the names of a number of hotels or apartments meeting the requirements, and from this list a selection can be made with better judgment.

No fees or charges of any kind will be required by the subcommittee on hotels or the Bureau, but a satisfactory guarantee is asked to assure that the rooms will be used at the time specified in the contract. The Bureau will issue reservation certificates guaranteeing the holder hotel accommodations in accordance with his request, on receipt of application accompanied by $5. This deposit shall apply as part or in full payment for any accommodations or services furnished.

Visitors will be met by uniformed guides of the Bureau, who will furnish strangers with any information desired. Those who arrive in the city without having made hotel reservations will be directed to the Hotel Registration Bureaus which will be established at convenient points and which will assign visitors to hotels in accordance with the rate they desire to pay. Transportation of passengers from the depot bureaus will be provided by the Universal Bus and Taxi Company, which is officially endorsed by the Hotel Association and which will provide a uniform means of conveyance to the hotels, rooming and apartment houses of the city. This service will be extended over definitely prescribed areas, and the charge for each passenger, including hand baggage, will be twenty-five cents.

Railroad Rates to San Francisco

From eastern points to San Francisco, Oakland, Los Angeles and San Diego, round trip excursion tickets will be on sale on and after March 1 to Nov. 30, 1915, with return limit of three months, but in no case later than Dec. 31, 1915. Stopovers will be allowed both going and returning within the final limit of ticket. On all tickets with San Francisco as the destination, reading in one or both directions through Los Angeles, a free side trip from Los Angeles to San Diego will be allowed, provided this is included in the ticket at the time of purchase—it will not be granted after arrival at Los Angeles or under other than the conditions stated. Tickets reading in one direction via Portland, Tacoma, Seattle, Victoria or Vancouver, will be on sale at a rate $17.50 higher than for direct lines both ways.

SOME RATES OF FARE TO SAN FRANCISCO

Boston (according to route to Mississippi Valley gateway)	$ 97.70-	$108.30
Chicago		62.50
Denver, Colorado Springs and Pueblo		45.00
Kansas City		50.00
Memphis, Tenn.		57.50
New York (Differential or Standard Lines)	94.30-	98.80
New Orleans		57.50
Omaha, Neb.		50.00
Philadelphia (Differential or Standard Lines)	92.95-	95.20
Portland, Me. (according to route to Mississippi Valley gateway)	102.70-	113.80
St. Louis		57.50
Washington, D. C.		92.30

Deaths

Theodore Potter, M.D. Medical College of Ohio, Cincinnati, 1887; a Fellow of the American Medical Association; president of the Indianapolis Medical Society in 1911; professor of principles of medicine and clinical medicine in the University of Indiana; attending physician to the Indianapolis City Hospital and consulting physician to the Protestant, Deaconess and St. Vincent's hospitals, Indianapolis; a member of the National Association for the Study and Prevention of Tuberculosis and one of the leaders in the antituberculosis movement in the state; a member of the Tuberculosis Hospital Commission; vice-president of the Indiana Society for the Prevention of Tuberculosis and secretary of the Marion County Society; died at his home in Indianapolis, February 8, from tuberculosis, aged 53. At a called meeting of the Indianapolis Medical Society, February 8, suitable action was taken regarding the death of Dr. Theodore Potter.

Edward Daniels Clark, M.D. University of Buffalo, 1909; a Fellow of the American Medical Association and a well-known young practitioner of Buffalo; for three years connected with the health department of that city, but since last September assistant to Dr. Fred. M. Meader, associate professor of preventive medicine in the College of Medicine of Syracuse University; First Lieutenant, M. C., N. G., N. Y., assigned to Sixty-Fifth Infantry and later transferred to Third Infantry; was found dead in his room in Syracuse, February 13, from the effects of an overdose of chloroform, aged 27.

Paul Pomeroy Allen, M.D. Medico-Chirurgical College of Philadelphia, 1909; a member of the Medical Society of the State of Pennsylvania and assistant secretary of the Medical Society of Franklin County; treasurer of the Cumberland Valley Medical Association; a member of the staff of the Chambersburg Hospital; acting inspector for the State Board of Health of Franklin County; health officer of the Borough; and one of the most promising young practitioners of Pennsylvania; died at his home in Chambersburg, February 10, from pneumonia, aged 29.

Eugene Grignon, M.D. University of Victoria College, Coburg, Ont., 1886; of Menominee, Mich.; formerly a Fellow of the American Medical Association; a member of the Michigan State Medical Society; for two terms coroner of Menominee County, health officer of Menominee, treasurer of Menominee County and judge of the probate court; while making a professional call in the country, January 31, was stricken with cerebral hemorrhage, and died in St. Joseph's Hospital, Menominee, February 2, aged 58.

Henry Frederick Wegener, M.D. Hahnemann Medical College, Chicago, 1874; since 1876 a teacher and high school principal; once president of the Denver Microscopical Society and Colorado State Teachers' Association; for the last seven years head of the science department of the Stadium High School, Tacoma, Wash.; died at his home in that city, February 5, from heart disease, aged 70.

William Fleming Breakey, M.D. University of Michigan, Ann Arbor, 1859; a member of the Michigan State Medical Society; for forty-four years clinical professor of dermatology and syphilology in his Alma Mater; director of the skin clinic of the University of Michigan Hospital; surgeon of U. S. Volunteers during the Civil War; fo[illegible] secretary of the local board of U. S. [illegible] Surgeons; died at his home in Ann A[illegible], [illegible] aged 79.

Edmund A. Chapoton, M.D. Detroit (Mich.) Medical College, 1875; a Fellow of the American Medical Association; clinical professor of principles and practice of medicine in the Detroit College of Medicine, and attending physician to St. Mary's Hospital, Detroit; a member of the Detroit Fire Commission from 1907 to 1913; and from 1888 to 1892, a member of the Detroit Board of Health; died at his home in Detroit, February 6, from heart disease, aged 62.

Lester Charles Mitchell, M.D. New York University, New York City, 1867; a veteran of the Civil War and later a practitioner of Joliet, Ill., and Minneapolis, Minn., and first superintendent of the Minnesota College Hospital; a prominent figure in the grain and milling interests of the Northwest; president of the Aberdeen (S. Dak.) Milling Company; died at the home of his daughter in Hamburg, N. Y., February 12, aged 72.

William Dugan Kelly, M.D. Harvard Medical School, 1903; of Boston; a member of the Massachusetts Medical Society; formerly president of the Boston Medical Society; medical inspector of schools and agent of the Municipal Board of Health of Boston; one of the founders of the clinic and milk station at Elizabeth Peabody House; died in the Carney Hospital, Boston, February 8, from septicemia, aged 34.

Harry Briscoe Vanatta, M.D. Medical College of Indiana, Indianapolis, 1896; a Fellow of the American Medical Association and a member of the Aesculapian Society of the Wabash Valley; formerly of Lerna, Ill.; aged 34; died in Mattoon, Ill., February 1, from the effects of a gunshot wound believed to have been self-inflicted while despondent on account of carcinoma of the stomach.

William Henry Gail, M.D. University of Buffalo, 1864; for many years a practitioner of East Aurora, N. Y.; local surgeon for the Pennsylvania System for thirty-four years; a medical cadet and assistant surgeon of the Eighteenth (N. Y.) Volunteer Cavalry during the Civil War; died at the home of his daughter in Buffalo, February 6, from heart disease, aged 74.

John Wesley Martin, M.D. (License, Kentucky, thirty-seven years' practice, 1893) a Forty-Niner and afterward a practitioner of Kentucky; surgeon of the Fourteenth (Ky.) Volunteer Infantry during the Civil War; who had been operated on in Cincinnati for cat[illegible]ew days before; died at his home in Ashland, Ky., February 3, from acute gastritis, aged 87.

John Franklin Davison, M.D. New York University, New York City, 1881; of Asbury Park, N. J.; for several years a member of the Asbury Park Board of Education and for one year its president; died at the Paul Kimball Hospital, Lakewood, N. J., February 2, after a surgical operation for disease of the intestines, aged 55.

Perry O. Guise, M.D. College of Physicians and Surgeons, Baltimore, 1882; for many years a member and clerk of the Board of Education of Findlay, Ohio; for two terms treasurer of Findlay and four years township clerk; died in the Home and Hospital, Findlay, February 9, from arteriosclerosis, aged 62.

Harry Paul Chambers, M.D. College of Physicians and Surgeons, Baltimore, 1891; a Fellow of the American Medical Association; surgeon to the Commonwealth Iron Company, Florence Iron Company, and Reserve Mining Company, Florence, Wis.; died at his home in Florence, February 9, aged 47.

Thomas Carney, M.D. Albany (N. Y.) Medical College, 1902; of Schenectady, N. Y.; a member of the Medical Society of the State of New York; and a major in the New York National Guard; died in Johns Hopkins Hospital, Baltimore, February 6, after an operation for disease of the stomach.

Casper H. Viehe, M.D. Homeopathic Medical College of Missouri, St. Louis, 1876; a member of the Indiana State Medical Association; an ordained minister of the Evangelical Lutheran Church; died at his home in Evansville, Ind., February 1, aged 78.

William H. Merrell, M.D. Bellevue Hospital Medical College, 1869; of South Branch and Somerville, N. J.; a member of the Medical Society of New Jersey and president of the Somerset County Medical Society; died in the Somerset Hospital, Somerville, February 9, from heart disease, aged 52.

Rufus Franklin Smith, M.D. University of Virginia, Charlottesville, 1881; for many years a practitioner and druggist of Easley, S. C.; president of the Easley Loan and Trust Company and chairman of the Board of School Trustees; died at his home in that place, February 3, aged 57.

John Henry Bird, M.D. College of Physicians and Surgeons, Chicago, 1884; for eight years assistant house physician of the Congress Hotel, Chicago, and later secretary and treasurer of the C. S. Hammond Publishing Company; died at his home in New York City, January 31, aged 73.

George W. Brown, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1868; prominent as an antislavery advocate and founder and editor of the *Herald of Freedom* and of the Conneautville, Pa., *Courier;* died at his home in Rockford, Ill., February 5, aged 94.

John Jasper Lake, M.D. Rush Medical College, 1857; a pioneer resident of DeWitt County, Ill.; for many years a practitioner, druggist and postmaster of Kenney, Ill.; died in the Odd Fellows' Old Folks Home, Mattoon, Ill., February 5, from senile debility, aged 85.

William E. Walker, M.D. Hahnemann Medical College, Philadelphia, 1891; died at his home in West Charleston, Maine, January 11, from a gunshot wound of the heart, self-inflicted it is believed with suicidal intent, while despondent on account of ill health, aged 50.

George E. Waller, M.D. Medical College of Virginia, Richmond, 1861; a surgeon in the Confederate service during the Civil War; for many years coroner and justice of the peace of Henry County, Va.; died at his home in Martinsville, Va., February 2, aged 76.

Richard Flavel Woods, M.D. University of Pennsylvania, Philadelphia, 1895; a Fellow of the American Medical Association; and a member of the Philadelphia Surgical and Philadelphia Obstetrical societies; died at his home in Philadelphia, February 10, aged 41.

Alexander McElroy Rea, M.D. Jefferson Medical College, 1865; assistant surgeon of U. S. Volunteers during the Civil War; for forty-seven years a practitioner of West Middletown, Pa.; died at his home in that place, February 2, from heart disease, aged 72.

J. J. Perry, M.D. University of Louisville, Ky., 1853; surgeon in the Confederate service during the Civil War; for forty-five years a physician of Texas; died at the home of his son in Hempstead, Tex., February 2, from senile debility, aged 87.

Charles Brooks Scott, M.D. University of Buffalo, N. Y., 1881; of Loudenville, Ohio; a member of the village council and of the board of education; a director of the Citizens' Saving Bank, Loudenville, and local railway surgeon; died at Knoxville, Tenn., January 27, aged 57.

Wilford Harris Gragg, M.D. Vanderbilt University, Nashville, Tenn.; 1879; University of Nashville, Tenn., 1880; for ten years superintendent of the Shelby County (Tenn.) Poor and Insane Asylum; died at his home in Gragg Station, Tenn., recently, from pneumonia, aged 61.

Calbe Winfrey, M.D. Washington University, St. Louis, 1847; for seventy-two years a resident of Jackson County, Mo.; surgeon in the Confederate Service during the Civil War; died in St. Joseph's Hospital, Kansas City, Mo., January 30, aged 91.

Jared D. Wetmore, M.D. Hahnemann Medical College, Chicago, 1882; formerly health officer of Yaquina Bay, Ore., and surgeon at the Siletz Indian Agency; died at his home in Portland, Ore., in December, aged 56.

John H. Jenkin, M.D. New York University, New York City, 1893; a member of the Medical Society of the State of New York; died at his home in Shrub Oak, N. Y., January 28, from cerebral hemorrhage, aged 45.

James H. Hoag, M.D. Hahnemann Medical College, Chicago, 1883; of Connersville, Ind.; while attempting to flag a traction car near Connersville, January 24, was struck by the car and died four hours later.

Alfred Napoleon Culberson, M.D. Tennessee Medical College, Knoxville, 1909; of Evens, Ga.; charged with an attack on a woman; was shot and killed by a posse of citizens near Evens, February 4, aged 35.

Kurt Seyferth, M.D. University of Maryland, Baltimore, 1885; formerly professor of languages in Baltimore City College; died at his home in Baltimore, January 9, from disease of the liver, aged 62.

Thomas Walter Taylor, M.D. University of Louisville, 1845; said to be the oldest practitioner in Kentucky; died at the home of his daughter in Henderson, Ky., January 8, from pneumonia, aged 91.

John Wesley Mitchell, M.D. Bowdoin College, Brunswick, Maine, 1863; surgeon of U. S. Volunteers during the Civil War; died at his home in New Orleans, January 12, from arteriosclerosis, aged 78.

William James Allen, M.D. Baltimore University, 1886; a member of the Medical Society of the State of Pennsylvania; died at his home in Landisburg, Pa., Dec. 31, 1914, from nephritis, aged 53.

Henry F. Weis, M.D. University of Heidelberg, Germany, 1863; surgeon of U. S. Volunteers during the Civil War; died at his home in Dayton, Ohio, January 26, from cerebral hemorrhage, aged 84.

John Lloyd McKay, M.D. Philadelphia University of Medicine and Surgery, 1870; of King's Mountain, N. C.; died at the sanatorium at Gastonia, N. C., Oct. 2, 1914, from cerebral hemorrhage, aged 69.

Matthew W. Harvison, M.D. Bennett Medical College, Chicago, 1898; one of the owners of the Harvison Hospital, Palouse, Wash.; died at Los Angeles, January 24, from tuberculosis, aged 52.

William F. Spence (license, Miss., 1882); a practitioner since 1860; for many years health officer of Hancock County, Miss.; died at his home in Caesar, Miss., January 10, from pneumonia, aged 73.

Joseph W. Wood, M.D. University of Louisville, Ky., 1868; for fifty years a practitioner of Metcalfe County, Ky.; died at the home of his daughter in Edmonton, Ky., January 9, aged 79.

Thomas S. Evans, M.D. Vanderbilt University, Nashville, Tenn., 1875; a Confederate veteran; died at his home near Flat Woods, Tenn., January 21, from nephritis, aged 72.

William G. Wilson, M.D. University of Maryland, Baltimore, 1852; for nearly half a century a practitioner of Shelbyville, Ill.; died at his home in that city, January 16, aged 87.

Edwin C. Thompson, M.D. Western Reserve University, Cleveland, Ohio, 1885; died at his home in West Liberty (Slippery Rock), Pa., January 9, from pneumonia, aged 53.

William H. Sherwood, M.D. Western Reserve University, Cleveland, Ohio, 1873; died at his home in Unionville, Ohio, January 26, from cerebral hemorrhage, aged 62.

Homer Dwight Hodge, M.D. University of Michigan, Ann Arbor, 1887; of Jackson, Mich.; died in the Jackson State Hospital, January 26, from paralysis, aged 60.

Thomas J. Spurlock, M.D. Eclectic Medical Institute, Cincinnati, 1856; of McComb, Miss.; died at the home of his son in Summit, Miss., January 22, aged 84.

James Wellington Starr, M.D. Cincinnati College of Medicine and Surgery, 1881; died at his home in Montpelier, Ohio, January 14, from arteriosclerosis, aged 61.

George O'Donnel Walton, M.D. McGill University, Montreal, 1873; for forty years a practitioner of Barbadoes, B. W. I.; died at his home recently, aged 71.

Landon A. Beale, M.D. Missouri Medical College, St. Louis, 1886; was found dead in his office in St. Louis, January 29, from heart disease, aged 47.

John C. Marshall, M.D. Louisville, Ky., Medical College, 1892; of Chuckey, Tenn.; died at his old home in Newmansville, Tenn., Dec. 30, 1914, aged 50.

J. Henry Brooks, M.D. Georgetown University, Washington, D. C., 1865; died at his home in Washington, January 29, from cerebral hemorrhage, aged 74.

Elizabeth Ellis, M.D. Harvey Medical College, Chicago, 1902; died at her home in Burns, Ore., Oct. 15, 1914, from cerebral hemorrhage, aged 60.

Marvin C. Wood (license, Utah, 1906); a practitioner since 1899; died at his home in Kanab, Utah, Dec. 29, 1914, from cerebral hemorrhage, aged 60.

Francis E. Carpenter, M.D. Jenner Medical College, Chicago, 1903; died at his home in Chicago, Dec. 28, 1914, from nephritis, aged 61.

Marie Jean Stees, M.D. Illinois Medical College, 1898; died at her home in Chicago, February 4, aged 53.

Cornelius F. Dowd, M.D. University of Pennsylvania, Philadelphia, 1867; died at his home in Willow Springs, N. C., Nov. 26, 1914, aged 74.

Michael William Kelleher, M.D. Bellevue Hospital Medical College, 1885; died at his home in Chicago, January 30, from nephritis, aged 58.

Frank S. Sovreen, M.D. New York Homeopathic Medical College, New York City, 1880; died at his home in Evart, Mich., Oct. 4, 1914.

John Morgan Howe, M.D. New York Homeopathic Medical College, 1879; died at the home of his son in New York City, Nov. 13, 1914.

Manley Horatio Sprague, M.D. Columbus, Ohio, Medical College, 1880; died at his home in Ottumwa, Iowa, January 13, aged 61.

Arthur Hubert Martel, M.D. Laval University, Montreal, Que., 1902; died at his home in East Angus, Que., Nov. 24, 1914, aged 38.

David Hammell, M.D. Long Island College Hospital, Brooklyn, 1877; died at his home in Detroit, Mich., January 23, aged 66.

Alvin P. Sawyer, M.D. Hahnemann Medical College, 1880; died at his home in Chicago, February 3, from nephritis, aged 59.

Abner Mulholland Rosebrugh, M.D. University of Toronto, Ont., 1859; died at his home in Toronto, Nov. 26, 1914, aged 79.

Andrew Dixon Packer, M.D. Long Island College Hospital, Brooklyn, 1908; died at his home in Brooklyn, February 1, aged 35.

George W. Deweese (license, Indiana, years of practice, 1897), died at his home in Fredericksburg, Ind., Nov. 3, 1914, aged 76.

Robert Bowen, M.D. American Medical College, Cincinnati, 1853; died at his home in Berlin, N. J., Dec. 12, 1914, aged 87.

Columbus V. Wedding, M.D. University of Louisville, Ky., 1879; died at his home in Kansas City, Mo., January 26, aged 60.

Freeland L. Etter (license, Texas, 1902), a colored practitioner of Harris, Tex.; died in Dallas, Tex., Oct. 25, 1914.

William J. Murphy, M.D. Albany, N. Y., Medical College, 1881; died recently at his home in San Bernardino, Cal.

Alexander Jenks (license, Kan., 1901), of Hanover, Kan.; died in the Topeka State Hospital, January 24, aged 71.

John W. Ruble (license, Tenn., 1889), died at his home in Del Rio, Tenn., January 21, aged 64.

Marriages

Henry Wise Wood, M.D., Maben, W. Va., to Miss Mamie Estella Warrener of Athens, Ohio, at Washington, D. C., Dec. 22, 1914.

George Reese Satterlee, M.D., New York City, to Miss Mabel Alger Powell of Ghent, N. Y., in New York City, February 9.

Frederick Melville Horsley, M.D., Lovington, Va., to Miss Laura Stringfellow Boyd of Farmville, Va., January 27.

Gilbert De Witt Dare, M.D., Morrisonville, N. Y., to Miss Mabel Claire Hancock of Colorado Springs, Colo, February 6.

Franklin Edward Murphy, M.D., to Miss Cordelia Antoinette Brown, both of Kansas City, Mo., February 16.

P. A. Surg. Ausey Hamilton Robnett, U. S. N., to Miss Mary Louise Manifor of Las Animas, Colo., January 21.

Henry Bush Beeson, M.D., Hannibal, Wis., to Miss Ann Elizabeth Urquhart of Medford, Wis., February 10.

William White McKenzie, Salisbury, N. C., to Miss Florence Robinson of New Orleans, February 1.

P. A. Surg. John Bowdoin Mears, U. S. N., to Miss Eulalie Mary Kahle of Elkton, Va., January 23.

William Roy Owen, M.D., to Miss Johanna Skogmo, both of Manford, N. Dak., February 1.

Howard Tracy Langworthy, M.D., to Miss Eva A. DaVoll, both of Brooklyn, February 10.

Irving Freiler Stein, M.D., to Miss Lucile Oberfelder, both of Chicago, February 20.

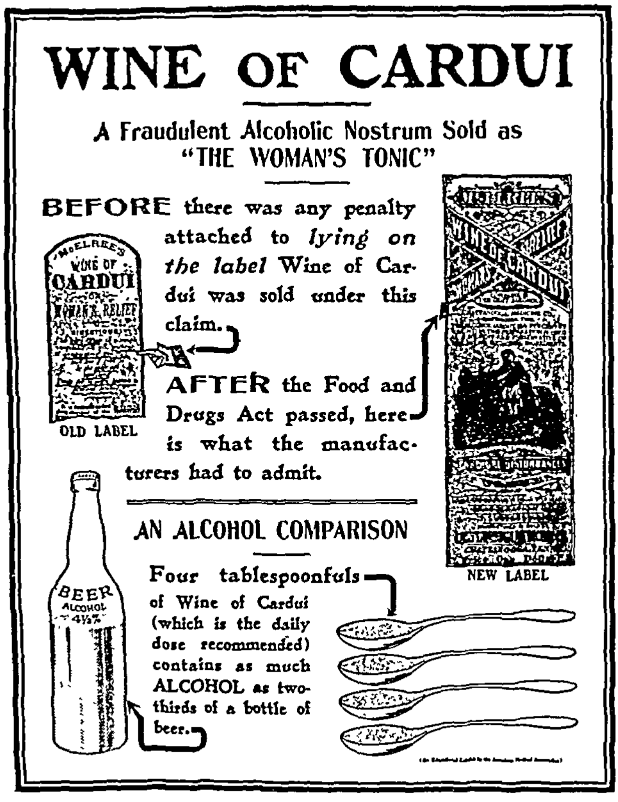
The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

WINE OF CARDUI[1]

The Company Solicits the Medical Profession for Testimonials to its Nostrum

Readers of THE JOURNAL are familiar with the articles that have been published regarding Wine of Cardui, manufactured by the Chattanooga Medicine Company whose chief owner is said to be John A. Patten. After the appearance of THE JOURNAL's article in its issue of July 18, 1914, John A. Patten and the Chattanooga Medicine Company entered suit against the American Medical Association and the editor of THE JOURNAL for $300,000.



WINE OF CARDUI

A Fraudulent Alcoholic Nostrum Sold as "THE WOMAN'S TONIC"

BEFORE there was any penalty attached to *lying on the label* Wine of Cardui was sold under this claim.

AFTER the Food and Drugs Act passed, here is what the manufacturers had to admit.

AN ALCOHOL COMPARISON

Four tablespoonfuls of Wine of Cardui (which is the daily dose recommended) contains as much ALCOHOL as two-thirds of a bottle of beer.

For displaying the original, of which this is a miniature, Dr. Oscar Dowling, President of the Louisiana State Board of Health, has been sued for $25,000 by the Chattanooga Medicine Company. The Louisiana State Board of Health upholds its president and declares Wine of Cardui a fraudulent nostrum pernicious and baneful in effect.

Since this suit was brought the same concern has sued one of the trustees of the American Medical Association, Dr. Dowling, for $25,000 because he, as President of the Louisiana State Board of Health, exhibited in the Health Exhibit Train, sent out by the state of Louisiana, an educational placard (which we reproduce in miniature on this page) dealing with Wine of Cardui. Still later, the concern entered suit against *Harper's Weekly* for $200,000 for the publication of matter regarding Wine of Cardui.

Wine of Cardui retails for a dollar a bottle and according to all reports it is a good seller. For years the profits accruing from the sale of this nostrum have been used lavishly in many directions. The power that comes with great wealth easily and not-too-scrupulously acquired, has been evident since the filing of these libel suits.

In THE JOURNAL for Sept. 12, 1914, a letter was published describing the alleged methods of the Chattanooga Medicine Company in its attempts to obtain from physicians favorable testimony regarding Wine of Cardui. This letter, written by a physician, gave what purported to be a conversation between another physician, whom we will call Dr. A, and a Wine of Cardui representative. Briefly, the story was that Dr. A had been told that the Chattanooga Medicine Company desired to retain him as an expert; that a retainer would be paid immediately for his services, and that if he would go before their attorney and make a deposition favorable to Wine of Cardui he would be paid $25 a day and expenses, and should his services be needed as an expert at the Chicago trial, he would be paid $50 a day and expenses for these services. Several months after this letter was published, Dr. A seems to have repudiated the conversation reported to have taken place between himself and the Wine of Cardui representative and to have warmly espoused the cause of the "patent medicine" concern's agent. Without going into details at this time regarding this matter, it is pertinent to note that in the interim between THE JOURNAL's publication and Dr. A's "repudiation," certain incidents had occurred locally. Dr. A, who is not a member of his local society, seems to have taken umbrage at some of the other physicians in his town who are members of the local organization. The details in this case may be gone into more fully at another time.

That the Chattanooga Medicine Company is very busy throughout the South attempting to get physicians to express themselves favorably to the Wine of Cardui nostrum, is quite evident. We give a few letters that have been received in this connection. This from a physician in Missouri:

> "A gentleman came into my office and after having been seated, inquired if I had ever used Wine of Cardui in my practice. I replied that I had not. He then asked me if, as a druggist, I had noted good from its sale and use in the way of saving doctors' bills for suffering ladies. I told him I believed every word THE JOURNAL had published about Wine of Cardui, and he said that his company would be able to show that it had done a wonderful lot of good and that later I would find the Association facing a court order and injunction, and they courted investigation; in fact insisted upon having justice in this matter. I dismissed him with the remark that I believed Wine of Cardui one of several colossal frauds foisted on suffering and trustful humanity and that I wanted to see justice prevail. He bade me good day remarking, 'Doctor, you may later have reason to know that you have been wrongly informed.' Had I acted differently, I believe I could have learned more, but I could hardly contain myself. I believe they are making a systematic hunt for anything that will sustain their suit."

And this from a physician in Illinois:

> "I wish to mention that the Chattanooga Medicine Company is dubiously soliciting signatures to prove that their preparation is not sold as a beverage. Agent wanted me to sign that I did not know that Wine of Cardui was sold as a beverage. I refused."

This from a physician in Virginia:

> "I wish to commend your work in exposing 'patent medicine' frauds and I am particularly interested in the Wine of Cardui suit. A few days since a winsome young woman (a Miss Ervin) from Chattanooga came through this section soliciting the profession for testimonials showing the merits of Wine of Cardui. Such 'nerve' is hard to imagine. She visited most of the men in this section but I know of but one from whom she obtained a testimonial. Later I learned *that the* young woman is a lawyer and that such testimonials are to be introduced as evidence in the suit of Wine of Cardui against the American Medical Association."

While this is from a physician in Arkansas:

> "Yesterday I was told by a *salesman for the* Chattanooga Medicine Company that they were going to have five thousand doctors' testimonials in their suit against you regarding the merits of *Wine of* Cardui. *He said all* these doctors would be graduates of reputable medical colleges but, of course, failed to state how they were going about getting these testimonials."

The letter that follows, while somewhat of the same nature as the preceding *ones, is* especially interesting for reasons that will soon be apparent. It comes from a physician in Louisiana:

> "Yesterday, a representative of the Chattanooga Medicine Company whose name is J. G. Cairns and *who lives in* Chattanooga, Tenn.,

---

[1] See editorial p. 744.

called to get me to give my opinion on Wine of Cardui. I told him I knew nothing about the concoction from *personal* experience, as I *never had a patient whom I knew to* take it, but that I accepted the criticisms of The Journal of the American Medical Association. He said he was interviewing the physicians all over the country asking them for the very worst opinion they have of Wine of Cardui. He said that in some parts of Alabama and Tennessee the doctors prescribed 'The Woman's Tonic.' Whereupon I asked him if he would have a physician to attend a sick member of his family who would prescribe Wine of Cardui and he said: 'If I lived in the back-woods, remote from good ethical doctors I'd have to consult them or none.' He further said only country doctors prescribe Wine of Cardui. He said he was looking after the legal part of the Chattanooga Medicine Company's business, appearing to want to leave the impression that he was a lawyer, but upon my putting the question direct he admitted that he is not a lawyer. I did not instruct him to not quote me in the opinion I gave, but feel sure he will not."

It would be interesting to learn whether the J. G. Cairns who is alleged to be interviewing physicians in the interest of the Chattanooga Medicine Company is the Rev. J. G. Cairns, who, according to Chattanooga newspapers, was arraigned last November before a trial committee of the Holston Methodist Conference on charges of "lying," "dishonesty" and "irregularities in the administration of the Alton Park church building fund." J. G. Cairns, the minister, was exonerated of these charges at the same time and by the same conference that extended a "whitewash" to John A. Patten, and the Wine of Cardui business. After his exoneration, J. G. Cairns was made associate pastor of Mr. Patten's church, the First Methodist Church of Chattanooga. Our readers will remember that the former pastor of this church, the Rev. C. H. Myers, did not sympathize with the methods by which Mr. Patten made his money or with the influence this money exercises in the church. Mr. Myers was removed from his pastorate at the same conference that exonerated Cairns and Patten. As recently as February 1, the Rev. J. G. Cairns has come to the open defense of John A. Patten in a letter to the Chattanooga *Times*, a paper that appears to be the mouthpiece of Patten and his interests. Mr. Cairns rebuked a local politician—unnamed—for opposing Mr. Patten who, according to Cairns, had granted to the politician "favors, political and financial." It might be a matter of interest to Methodism to determine whether J. G. Cairns of the First Methodist Church of Chattanooga is on the pay roll of the Chattanooga Medicine Company. If the Rev. J. G. Cairns is the same person as the J. G. Cairns referred to by our correspondent then the nice problem presents itself: Can the position of associate pastor to the First Methodist Church of Chattanooga be adequately filled by a man who is traveling around the country in behalf of the Chattanooga Medicine Company and Wine of Cardui?

Harper's Weekly for Feb. 27, 1915, has another article on Wine of Cardui referring specifically to Mr. Patten's suit. In commenting on the attempts of the Chattanooga Medicine Company to get physicians to testify to the value of Wine of Cardui, *Harper's* says that the methods of the concern, while shrewd and "slick," fail to take into account the honesty of physicians. It believes that while some few doctors may be willing to barter their professional reputations for a mess of pottage, the great majority will not be. *Harper's* correctly appraises the medical profession.

LOUISIANA STATE BOARD ACTS

Apropos of what is published above is the following, which appeared in the *New Orleans Item*, Feb. 18, 1915.

HEALTH BOARD HITS AT WINE OF CARDUI

Backs Dowling In Holding It Pernicious; War on Others

Branding Wine of Cardui as being "among the most fraudulent" of "nostrums pernicious and baneful in effect" the State Board of Health Thursday afternoon endorsed by resolution the campaign of Dr. Oscar Dowling, president of the board, against it and other patent medicines.

"These nostrums are pernicious and baneful in effect," says the resolution in part. "The enormous profits accruing from the sale of so-called medicines are derived largely from the income of the very poor and the unfortunate. Among the most fraudulent of these preparations is Wine of Cardui, manufactured and sold by the Chattanooga Medicine Company, Chattanooga, Tennessee, and St. Louis, Missouri, as proved by analysis in the laboratory of the state board of health, the ingredients of this nostrum being alcohol and vegetable materials practically therapeutically inert.

"*Therefore be it resolved:* That the State Board of Health unanimously approves and supports the campaign against harmful patent and proprietary nostrums now being prosecuted by Dr. Oscar Dowling, the executive officer of this board.

"That he is authorized to push the campaign to the full extent of the law with the hope of destroying the baneful influence of the owners and manufacturers of the many noxious articles now offered to the public.

"That the exhibit placed on the Louisiana state board of health exhibit car which illustrates the fraudulent claims of Wine of Cardui and other patent preparations, has our full approval and commendation.

"That the suit by the Chattanooga Medicine Company, Chattanooga, Tennessee, brought against the president of the Louisiana State Board of Health as an individual, should have been filed against the president and executive officer of the State Board of Health and in the prosecution of this suit the Louisiana State Board of Health will give Oscar Dowling, its president and executive officer, cordial support and assistance to the limit of its power and resources.

"That we welcome the opportunity to assist in this suit, the outcome of which we are confident will be a death blow to the popular use of Wine of Cardui and all other fraudulent patent nostrums."

Correspondence

Cabot, Bernard Shaw, and the Medical Profession

To the Editor:—In the February number of *McClure's Magazine*, I am quoted in an article by R. H. Schauffler as backing Bernard Shaw's charges against the medical profession, except his attitude on animal experimentation. Shaw's attack is summarized in his own words, including the following sentence: "Most doctors have no honor and no conscience." Other sentences in Shaw's habitual exaggerative style follow, and my approval of them all is assumed. The facts of the matter are as follows:

In the *Survey*, June 3, 1911, I wrote, at the request of that magazine, a review of Shaw's play entitled, "The Doctor's Dilemma," and said that as regards "Mr. Shaw's principal theses and in the main, I find myself heartily in agreement with him." I did not suppose that any one would take Shaw seriously enough as to suppose that a ridiculous calumny, such as the statement that "most doctors have no honor and no conscience" would be regarded as a significant or an important remark. It should go without saying that I have no sympathy with such a statement, as I believe the medical profession to be as honorable and conscientious a body of men as any in the country. In the article on which Mr. Schauffler's misstatement of my position is founded, I summed up what in my opinion were the main offences of our profession, offences which we all recognize and deplore. I specified such shortcomings as these: that we do not tell patients with sufficient vigor the truth about their habits and their own responsibility for disease; that we sometimes foster cases of imaginary illness; that we sometimes perform unnecessary operations; that fee splitting and other abuses are widespread. No one, I suppose, will doubt these facts and no one will have much doubt that they will continue as long as the doctors of the country are as miserably poor as at present. So long as the economic status of the doctor is what it is, we cannot look for much improvement in that direction.

This was Shaw's belief about the whole matter and it is mine. It is not a question of blaming anybody but of getting something done. That "something" is raising of the standards of examining boards for the license to practice medicine. This is what the medical profession can do, of itself, and do immediately. It cannot, of itself, carry out the other greatly needed reform which I believe is coming through the more intelligent activity of hospital trustees, namely, the payment of hospital physicians for full time work and the selection of these physicians by methods that exclude favoritism and the methods of the close corporation.

I should add that I understand perfectly Mr. Schauffler's unintentional mistake in the statement of my position. He is a man for whom I have the greatest admiration, and I am sure he would not willingly misrepresent any one.

Richard C. Cabot, M.D., Boston.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

DENATURED ALCOHOL FOR EXTERNAL USE

To the Editor:—In The Journal, Jan. 2, 1915, p. 72, it is stated that the external use of any alcohol containing wood spirits is unsafe.

When denatured alcohol first came out, we very cautiously began the use of it for external use, in place of grain alcohol. After a very extended experience covering the use of at least ten barrels, we are justified in stating that it takes the place of grain alcohol in all rubbings and for wet dressings for wounds. We have never seen the slightest trace of poisoning following its use, and we now never use grain alcohol for either of these purposes. We certainly think that the idea that denatured alcohol is poisonous for external use is erroneous and is not based on facts of its use.

F. E. Clough, M.D., Lead, S. Dak.

Answer.—The caution against the use of denatured alcohol has been made by The Journal on the ground that while bad results may occur only in a very small number of cases, it is better to employ a perfectly safe preparation. It is probable that this statement should have been made with some qualification.

Although clinical reports indicate decided danger to the digestive apparatus, nervous system, eyesight, etc., from intoxication due to the use of methyl alcohol (especially of deodorized methyl alcohol) for such external uses as massage of the skin, yet in all probability the employment of "denatured" (methylated) alcohol is, for these external uses, harmless. It is not at all likely that sufficient methyl alcohol is absorbed into the system by occasional rubbings with denatured alcohol (which, like the British and German mixtures, contains about 10 per cent. of crude methyl alcohol) to produce untoward effects. However, *wet* dressings of wounds with denatured alcohol offer a better chance of minor intoxications than rubbings.

ETHYLHYDROCUPREIN

To the Editor:—Please discuss the chemistry and pharmacology of ethylhydrocuprein.

T. E. Fuller, M.D., Texarkana, Texas.

Answer.—Ethylhydrocuprein hydrochlorid is a chlorid of ethylhydrocuprein, a derivative of the base cuprein derived from the bark of China Cuprea. Ethylhydrocuprein is closely related to quinine, differing from the latter in that it contains an ethoxy group instead of a methoxy group, and contains two more atoms of hydrogen, which convert an ethenyl group into an ethyl group. Thus quinin has the formula $C_{20}H_{24}O_2N_2$ and ethylhydrocuprein the formula $C_{21}H_{28}O_2N_2$.

Cuprein is said to have an action very similar to that of quinin, but much weaker. The introduction of the ethoxy and ethyl groups, forming ethylhydrocuprein, make the action more pronounced, so that it is asserted that its action as an antimalarial agent is greater than that of quinin. For ethylhydrocuprein it is claimed, especially, that it has a specific action on pneumococcus infection by which it produces a curative effect in doses that are not injurious to the organism. R. Levy (*Berl. klin. Wchnschr.*, Dec. 30, 1912), after a number of experiments, concludes that it is possible to check and permanently cure an infection with *Streptococcus mucosus* after it has reached its full development, while the untreated control mice succumb to the bacteriemia in a typical manner. G. Izar and R. Nicosia (*Berl. klin. Wchnschr.*, March 9, 1914) report successful results in obstinate cases of malaria in which the use of quinin had been unsuccessful.

This preparation is exploited as a proprietary under the name Optochin, and is controlled by U. S. patent. Although the statements made in the literature are favorable to the preparation, they do not appear to have been confirmed.

OPIUM

To the Editor:—Dr. Macht's interesting chapter on the History of Opium (The Journal, Feb. 6, 1915, p. 477) recalled to my mind the rimed couplets given below. These were found written on a fly leaf of Wood and Bache's United States Dispensatory (Ed. 2, 1834) and are in the handwriting of my grandfather, Daniel R. Bailey, who graduated from the University of Pennsylvania in 1837. They were probably in common use among the students of that day and may have been published before.

OPIUM

This grand specific eases pain,
Produces sweat when dry the skin,
In doses small the frame excites
And puts to flight those sleepless nights.
When painful cough excites the breast
'Twill pain allay and cough arrest;
If morbid products need restrain,
We'd give it then in half a grain;
But if hard pain we would assuage,
Or calm the maniac in his rage,
We'd deal it then with liberal hand,
One grain to three the case demands;
But if we wish immediate rest,
We must procure the pure and best;
That species which from Smyrna comes
Is far the best of Thebaic gums;
'Tis large and soft, of grayish brown,
And covered with a leafy down.
The tincture, powder or the pill
Most indications will fulfil;
For weakly nurslings at the breast
The elixir proves to be the best;
But if phlogosis rage within
And burning heat affect the skin,
The salts of morphia, it is plain,
Would less excite the heart and brain.

Clifford B. Farr, M.D., Philadelphia.

LITERATURE ON ELECTRIC SHOCKS

To the Editor:—Please inform me if there is any recent literature or publication on the subject of electric shocks.

W. F. Plumley, M.D., Rochester, N. Y.

Answer.—In The Journal, March 15, 1913, p. 851, there was published a list of references on this subject. The following articles are subsequent to this list:

Brocx, D.: Fatal Electric Accidents, *Nederlandsch Tijdschr. v. Geneesk.*, 1914, lviii, No. 5.
First Aid to Those Overcome by Mine Gases, Electric Shock, etc., Miscellany, The Journal, Nov. 14, 1914, p. 1784.
Groler: Treatment of Heartstroke, Sunstroke and Electric Injuries, *Deutsch. med. Wchnschr.*, Jan. 1, 1914; abstr., The Journal, Feb. 14, 1914, p. 578.
Stewart, P.: Case of Hysterical Monoplegia Following Electric Shock, *Brit. Med. Jour.*, Dec. 20, 1913.
Report of Committees on Resuscitation from Electric Shock and Resuscitation from Mine Gases, Proceedings of the Conference of the American Medical Association on Medical Legislation, abstr., The Journal, Feb. 28, 1914, p. 724.
Stewart, P.: Case of Hysterical Monoplegia Following Electric Shock, *Brit. Med. Jour.*, March 7, 1914.

Work of Commission on Electric Shock, Current Comment, The Journal, Nov. 1, 1913, p. 1637.
Jellinek, S.: Electric Accidents, *Wien. klin. Wchnschr.*, Oct. 30, 1913.
Fisch, C. F.: Electric Accidents, *Wien. klin. Wchnschr.*, Sept. 4, 1913; abstr., The Journal, Oct. 11, 1913, p. 1417.

CORONER'S DUTY IN ALASKA

To the Editor:—1. What constitutes a coroner's case in Alaska?

2. Must each district have a coroner's physician, and is there any provision made for one?

3. Can a person be buried without a physician's death certificate or burial permit?

H. E. Auringer, M.D., Flat, Alaska.

Answer.—1. In Alaska a coroner can be appointed either by the President of the United States or by the judge of the Alaska district court. In the case of any sudden death or injury which is apparently due to crime or is a suicide or an attempted suicide, the coroner must investigate the circumstances and inquire by jury into the cause thereof.

30. Statutes at Large, Section 1325, et seq.

2. There seems to be no requirement that districts must have a coroner's physician, but it is provided that witnesses must be subpenaed to appear before the coroner's jury, and these witnesses must include a physician who is to inspect the body and give his opinion as to the cause of death. This serves the same purpose.

30. Statutes at Large, Section 1325, et seq.

3. There seems to be no specific provision in this regard. Doubtless the President or the officials under him in the executive department of the government, or even certain Alaska officials, could by rule require such. The powers as vested in the executive of the United States under the Public Health Service law would seem to warrant this conclusion. Application to the Public Health Service at Washington, D. C., would determine this point.

INK FOR WRITING ON GLASS

To the Editor:—Please give me a formula for a water-proof solution with which I can write on glass bottles and which will not rub off when carried loose in grip. White color. Black also.

R. L., Sidney, Iowa.

Answer.—A good ink for writing on glass may be made as follows:

White Ink: Mix 1 part Chinese white (water-color pigment) or barium sulphate with 3 to 4 parts sodium silicate solution (water glass). The sodium silicate solution should have the consistency of glycerin.

Black Ink: Mix 1 part liquid Chinese ink (or Higgin's Eternal Ink, or some similar carbon ink) with 2 parts sodium silicate solution.

Apply with an ordinary steel pen. The ink will dry in fifteen minutes and will withstand water. It may be readily removed by scraping with a knife.

ARTICLES ON ECZEMA

To the Editor:—I wish to get the names of authors and titles of papers bearing on the subject of eczema, its diagnosis and differentiations.

J. M. S.

Answer.—The following is a list of references on this subject:

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Colorado: Denver, April 6. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

Connecticut: New Haven, March 8-9. Sec., Dr. Charles A. Tuttle, 196 York St., New Haven. Homeopathic; New Haven, March 9. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven. Eclectic: New Haven, March 9. Sec., Dr. T. S. Hodge, 19 Main St., Torrington.

Florida: Homeopathic, Jacksonville, March 5, Sec., Dr. C. W. Johnson, 33 E. Monroe St., Jacksonville.

Idaho: Lewiston, April 6. Sec., Dr. John F. Schmershall, Jerome.

Maine: Portland, March 9-10. Sec., Dr. F. W. Searle, 776 Congress Street.

Massachusetts: Boston, March 9-11. Sec., Dr. Walter P. Bowers, Room 501, No. 1 Beacon St., Boston.

Minnesota: Minneapolis, April 6-8. Sec., Dr. Thomas S. McDavitt, Lowry Bldg., St. Paul.

Missouri: St. Louis, March 22-24. Sec., Dr. J. A. B. Adcock, State House, Jefferson City.

Montana: Helena, April 5. Sec., Dr. William C. Riddell, Helena.

Rhode Island: Providence, April 1-2. Sec., Dr. Gardner T. Swarts, 315 State House, Providence.

Utah: Salt Lake City, April 5-6. Sec., Dr. G. F. Harding, 407 Templeton Bldg., Salt Lake City.

Ohio Reciprocity Report

Dr. George H. Matson, secretary of the Ohio State Medical Board, reports that 28 candidates were licensed through reciprocity from Oct. 22 to Nov. 18, 1914. The following colleges were represented:

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
Chicago College of Medicine and Surgery	(1912)	Kansas
Hahnemann Medical College and Hospital, Chicago	(1913)	Illinois
Rush Medical College	(1913)	Illinois
Indiana University	(1912)	Indiana
Physio-Medical College of Indiana	(1902)	Indiana
Baltimore Medical College	(1903)	Indiana
College of Phys. and Surgs., Baltimore	(1907) (1912,2)	W. Virginia
Detroit College of Medicine and Surgery	(1914)	Michigan
University of Michigan, Dept. of Med. and Surg.	(1901) (1914,3)	Indiana; Michigan.
University of Michigan Homeopathic Medical College	(1906) (1912) (1913) (1914)	Michigan.
St. Louis University	(1913)	Missouri
New York Homeo. Med. Coll. and Flower Hosp.	(1903)	New York
Cleveland Homeopathic Medical College	(1905)	Michigan
Starling Medical College	(1897)	W. Virginia
Jefferson Medical College	(1906) (1913)	Penna.
University of Pennsylvania	(1911) (1913)	Penna.
University of Pittsburgh	(1913)	Penna.
Medical College of Virginia	(1909)	Virginia

Arkansas Reciprocity Report

Dr. W. S. Stewart, secretary of the State Medical Board of the Arkansas Medical Society, reports that 17 more candidates were licensed in Arkansas, through reciprocity, during 1914. The following colleges were represented:

College	Year Grad.	Reciprocity with
University of Alabama	(1911)	Mississippi
George Washington University	(1912)	Oklahoma
Georgia College of Eclectic Med. and Surg.	(1908)	Georgia
University of Georgia	(1906)	Georgia
Chicago Coll. of Med. and Surg.	(1910)	Illinois
Rush Medical College	(1884)	Indiana
Indiana University	(1909)	Indiana
Hospital College of Medicine, Louisville	(1905)	Kentucky
Louisville and Hospital Medical College	(1908, 2)	Kentucky
Tulane University of Louisiana	(1910) (1913)	Louisiana Mississippi
University Medical College, Kansas City	(1908)	Oklahoma
Chattanooga Medical College	(1907)	Oklahoma
Meharry Medical College	(1914)	Oklahoma
University of Tennessee	(1900)	Oklahoma
Vanderbilt University	(1886)	Oklahoma

Minnesota October Report

Dr. Thomas S. McDavitt, secretary of the Minnesota State Board of Medical Examiners, reports the oral, practical and written examination held at Minneapolis, Oct. 6-8, 1914. The total number of subjects examined in was 17; total number of question asked, 80; percentage required to pass, 75. The total number of candidates examined was 9, of whom 8 passed and 1 failed. Ten candidates were licensed through reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Northwestern University	(1914)	90.1
Rush Medical College	(1913) 92.9; (1914) 82.4, 86.3, 87.1,	94.1
University of Minnesota	(1914)	89.3
University of Pennsylvania	(1914)	85.9

FAILED

College	Year Grad.	Per Cent.
Milwaukee Medical College	(1909)	67.1

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
George Washington University	(1910)	Dist. Colum.
College of Phys. and Surgs., Chicago	(1910) (1912)	Illinois
Northwestern University	(1911)	Illinois
State University of Iowa, College of Medicine	(1901)	Iowa
Harvard University	(1914)	Wisconsin
Western University	(1913) (1914)	Ohio
Milwaukee Medical College	(1903)	N. Dakota
Queen's University	(1892)	Iowa

Kentucky December Report

Dr. A. T. McCormack, secretary of the State Board of Health of Kentucky, reports the written examination held at Louisville, Dec. 16-18, 1914. The total number of subjects examined in was 11; total number of questions asked, 110; percentage required to pass, 75. The total number of candidates examined was 13, of whom 9 passed and 4 failed. Two candidates were given reregistration licenses. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
University of Louisville	(1914)	83
College of Phys. and Surgs., Baltimore	(1914)	85
Johns Hopkins University	(1911)	79
Syracuse University	(1911)	90
Ohio-Miami Medical College	(1914)	83
Lincoln Memorial University	(1914)	80
Meharry Medical College	(1912)	78
University of Tennessee	(1906)	83

Book Notices

With Sabre and Scalpel. The Autobiography of a Soldier and Surgeon. By John Allan Wyeth, M.D., LL.D. Cloth. Price, $3 net. Pp. 535, with illustrations. New York: Harper & Brothers, 1914.

"The chief purpose of this volume is to record from personal observation something of the social, economic and political conditions which prevailed in the South before, during and immediately after the Civil War." This is the introductory sentence of the introduction. The book is not strictly an autobiography; one is compelled to refer to a brief biography, in the form of an appendix, to learn even when and where the author was born. In the body of the book Dr. Wyeth speaks of visiting Dr. J. Marion Sims, in Paris, "at which time I met for the first time his youngest daughter, named Florence Nightingale"; but he does not say that she later became Mrs. John A. Wyeth. This, however, one learns from the appendix. There is a lack of consecutiveness; in one of the first chapters, of four or five pages, we are carried from the time when, as a boy of 4, he began to ride horseback, to the tragedies of the war, when he lost his favorite horse, "Fanny." In the next chapter we again are carried back to his boyhood days where we are told about "Major," king among dogs, and the battles he had won, and forward again to the Civil War. But this is not a fault, although the method has resulted in some repetition. These chapters of experience are candidly and unaffectedly written, are full of human interest, and are more interesting than would be a formal, consecutive autobiography.

Dr. Wyeth's description of the social and economic conditions in the South as they existed in his boyhood days is startling in the revelation as to what changes can take place in the span of one human life. His discussion of the slavery question is conservative and dispassionate—much more so than could have been the case if written fifty years ago. He asserts that there was a period in the decade from 1830 to 1840 when the solution of the problem was possible, when there were emancipation societies organized in the South. He is convinced that if "the conservative and better portion" of the North "had united in earnest and friendly cooperation with their brothers of the South" the tragedy of the rebellion would never have been enacted. The author was less than 17 years of age when he became an active participant in the war. In those chapters devoted to the Civil War he graphically describes the life and experience of a private soldier in the army, in battles and in prison. His prison experience was in Camp Morton, Indianapolis, where he was sent, Oct. 15, 1863, when only 18, and where he remained until February, 1865. For three years after the war, he was engaged in farming, contracting, etc., and in 1867 took up the study of medicine, graduating in 1869. But he did not practice long. His first fatal case convinced him that he was not yet prepared; so two months after he put up the shingle he pulled it down and went to Arkansas to make money to take up postgraduate work. Later he went to New York, graduated from Bellevue in 1873, and entered on his professional life's work.

Part II is devoted to medical matters, and is the part that will be of special interest to the medical, rather than to the lay, reader. In this Dr. Wyeth discusses the founding of the polyclinic, refers to his work on the carotid artery, to his bloodless hip-joint and shoulder operations, and to other surgical and professional matters.

Few men have had such a varied experience; here is the list of his occupations, as outlined in the book: farmer, woodsman, Confederate soldier, cotton planter, cattle buyer, medical student, river pilot, building contractor, land speculator and telegraph operator. On top of this came his medical career, in which he has made a name comparable with any in the annals of American surgery. Chapters from the life of such a man, presenting his experiences, adventures and observations, are indeed welcome. The book is not "dry"; even when discussing slavery and the war, and when telling of the obstacles that were met and overcome, there is continually being interjected some amusing incident, some story to amuse and enlighten the reader.

The Anatomy of the Human Skeleton. By J. Ernest Frazer, F.R.C.S., Lecturer on Anatomy in the Medical School of St. Mary's Hospital. Cloth. Price, $6.50. Pp. 274, with 219 illustrations. Philadelphia: P. Blakiston's Son & Co., 1914.

This book deals with the whole skeleton—bones, joints and ligaments—together with the other structures immediately associated. The point of view is that of a mechanician studying a machine and the way it works—the harmonious cooperation of all the parts, each adapted to the other and each influencing the other. The bones are not considered as individual structures, isolated from others and laid each by itself on the table, but "each part of the skeleton has been used as a peg on which to hang a consideration of the neighboring structures." It is the full-grown machine which is studied, and this is done with care and thoroughness. The emphasis is laid on the mechanical and physical factors of its working. Each phase of action is considered and profusely illustrated. Nearly all the illustrations are from original dissections, and are mostly colored. They show well the various phases of activity of each part of the skeleton, always as it exists in the body surrounded by the other structures which work with it. These illustrations are excellent. They bring out interesting relations not often noted, and constitute a valuable contribution to anatomic illustration. The influence of the associated structures on the form and the working of the skeletal structures is clearly shown. Thus each bone is shown to have a primitive form due to inheritance and ontogenetic development, and also a surface molding due to the action on it of muscles and to a lesser extent of vessels, nerves, etc. The book is evidently the product of much personal work and study by the author directly over the structures themselves. It is not a study of the literature but of the things. It is original. There are no references to the literature in the whole work. In some respects it is rather to be regretted that the literature is not considered more carefully. In the brief references to embryology and evolution the author has omitted from consideration some interesting and important contributions. Thus, in his reference to the development of the acetabular cavity, page 123, he takes no account of the os acetabuli, discovered by Albinus. A consideration of this bone, and of the excellent papers of Rambaud, of Renault and of Amantini, would have modified greatly his explanation of the existence of the ligamentum teres femoris. And in his account of the "hypothetical" evolution of paired limbs in vertebrates, beginning on page 61, there is no consideration of the theory of Gegenbaur, nor any mention of the continuous lateral fin fold theory of Thacher, Balfour and Mivart. From the point of view of embryology, comparative anatomy and evolution, the student will get more from the many classic books and papers on those subjects. The author of this book does not present things from that aspect. But students, physicians and especially surgeons, who wish to understand thoroughly the working of the skeletal machine, and the way in which not only the form of its parts but also its mechanical qualities of strength, elasticity, etc., contribute to the efficient working of the body as a whole, will find in this book much that is interesting and valuable.

Laboratory Manual for the Detection of Poisons and Powerful Drugs. By Dr. Wilhelm Autenrieth, Professor in the University of Freiburg. Authorized Translation of the Fourth German edition by William H. Warren, Ph.D., Professor of Chemistry in Wheaton College. Cloth. Price, $2 net. Pp. 320. Philadelphia: P. Blakiston's Son & Co., 1915.

The present edition presents the subject in a handy volume, and describes the systematic detection of poisons in a clear and sufficiently exhaustive manner. Quantitative methods are given, and some of the more recent biologic tests find their place among the older standard methods. Among these may be mentioned the test for arsenic by growth of *Pencillium brevicaule* and the serum test for human blood. Tests for a considerable number of alkaloidal substances, not usually included as poisons, are described, and the modern synthetics are quite comprehensively treated. A feature which will be attractive to students of pharmacy is the inclusion of a number of assay processes from the German Pharmacopeia. The method of Reinsch, which is very convenient as a preliminary test for the use of physicians, receives no mention. The descriptions and directions for the various processes are clear and concise. Explanations of the theoretical aspects of the various processes are given in small type. This makes the book of some service in the teaching of general chemistry. The work of the translator has been well done—the literary style is good. The translator has introduced a somewhat fuller discussion of the subject of "normal arsenic" than was given in the original. He has also described a modification of the Gutzeit method for the quantitative estimation of arsenic as worked out by Professor Sanger. It must be remembered that this is a laboratory manual, and hence presents none of the medicolegal considerations which are of such importance to the physician. A few pages devoted to plain directions for the procedure in cases of poisoning with regard to antidotal treatment, *intra-vitam* tests of urine, stomach contents, etc., and the collection and transmission of materials to the analyst, would greatly enhance the value of the work.

Miscellany

Poisoning by Tetrachlorethane

The progress of industry is always disclosing new dangers for the workers. A new form of poisoning was brought to light at an inquest, held in London, on a French-polisher employed in an aeroplane factory, whose duty was to apply to parts of aeroplanes a varnish bearing the trade name of Emaillite. He complained at times that the smell of the material affected him. The witnesses agreed that the fumes left an unpleasant taste in the mouth, especially in the morning. The deceased developed jaundice, and attributed it to the vapor from the varnish. He had begun to work at the factory in August, when pressure of work, owing to the war, caused a large increase in the output of the factory and in the staff. He left about the middle of October, when he looked very ill. About this time, also other workmen developed jaundice. It was noticed by the smell that the vapor from the varnish hung about in invisible clouds, so that one would walk into a patch of it quite a long distance from the place where it was being applied; also that the smell was much less noticeable at higher levels. The building was large and without partitions. The material was applied in one corner of the premises. Dr. W. H. Willcox, physician to St. Mary's Hospital, stated in evidence that he attended the deceased at the hospital for jaundice, nausea, and sickness mornings. There was slight pain in the upper abdomen. The liver was enlarged, but there was no sign of anemia, or alcoholic excess. He analyzed the varnish and found it was a mixture of methylated spirit, acetone, benzene and tetrachlorethane. He distilled the material, and found that the bulk of the liquid distilled over at between 63 and 80 C. (145.4 and 176 F.). It was volatile, and quickly evaporated, yielding a vapor 1.91 times heavier than air. On visiting the air-craft work, he was much struck by the way in which the vapors hung about even at a distance of 30 yards from where the material was being used. He placed white rats on perforated platforms in glass vessels, each containing a different constituent of the material and one the material itself, for eight hours a day for a week. After being kept in the vapor of the varnish and of the tetrachlorethane, the rats became drowsy and remained so after removal for some little time. After an hour or so they fed and became active, but did not gain in weight. In the acetone vapor the animal was drowsy, but gained in weight as the week advanced, and became normal at once when removed from the vapor. The same phenomena occurred in regard to the benzene, but in the methylated spirit the animal was not affected. After seven days' treatment the animals were killed. The rat kept in the tetrachlorethane vapor showed marked changes in the liver, signs of fatty degeneration and bile staining. The rat kept in the vapor of the material itself showed similar but less marked liver changes. In the other rats no changes were present to the naked eye. Microscopic examination of the rat exposed to tetrachlorethane showed fatty degeneration and bile staining and cloudy swelling in the liver and kidneys. Dr. Willcox recalled the case in which carbon tetrachlorid used as a hair wash proved fatal in London in 1909. The substance now under consideration was one of the same series and was a powerful poison. He had investigated other cases at the factory. Certain symptoms were common to all: drowsiness while at work, loss of appetite, nausea, vomiting, headache, a peculiar taste and irritation at the back of the throat, jaundice, with pale stools and high-colored urine, constipation generally, and no anemia. In a few cases the patients became delirious and severely ill. In one case there was conjunctivitis. In several cases the symptoms disappeared when the patient was absent from work, but on resuming they returned speedily in an aggravated form. In one case, a very severe one, the patient was very ill at the present time—there was much ascites, owing to cirrhosis of the liver. He found several workers in the factory suffering from unmistakable signs of the onset of the poisoning. They had loss of appetite, nausea and a tendency to sleepiness. He had no doubt that the illness could be entirely avoided by proper arrangements at the factory to get rid of the vapor. Two deaths were discovered at a later inquest also related to this cause. In one the subject was a young woman employed in an aeroplane factory who died from toxic jaundice with uremic symptoms, and the other subject was a girl of 19 who had intense jaundice and toxic degeneration of the liver was found. The government is taking energetic measures to prevent further accidents from this cause.

The Doctor's Bag

Perhaps nothing will better illustrate the change that has occurred in the practice of medicine during the past twenty-five or thirty years than to note the sort of appliances carried by the country doctor now as compared with former times. During the eighties the manufacturing pharmacists began the plan of supplying doctors, whether practicing in the city or country, with all their drugs in tablet form. When active drugs are used and the tablet contains but a single ingredient, or at most two or three, whose combination has a recognized value, there can be very little objection to this method of dispensing, and indeed much may be said in its favor. But soon all sorts of combinations of drugs appeared. Most of these are thoroughly unscientific or inert, or contain ingredients whose action is antagonistic to each other, and in most of them no one could anticipate what their action would be. This led to exceedingly loose prescribing and caused a habit in doctors inclined to be careless or hasty of giving the patient what the doctor had with him rather than what the patient's condition required.

Most country doctors filled their emergency bags with these tablets and carried little else. Indeed, the refinements in diagnosis which we now have did not exist, and prescribing was necessarily less accurate.

Lately we looked through the bag of a country doctor who tries to practice according to modern standards, and this is what we found: two soft catheters; a pocket case containing scissors, scalpels, lances and forceps; another small case containing an electric lamp and specula for examining the ear, nose and throat, and a magnifying glass; a Tycos sphygmomanometer; a Tallqvist hemoglobin scale; a pipet for counting the white corpuscles, and another for red corpuscles, with appropriate diluting fluids for each; a number of slides for making blood smears; two blood serum tubes and two agar slants; three tubes of old tuberculin for making the von Pirquet test; a hand-ball syringe; sterile gauze; cotton and bandages; a roll of adhesive plaster; a rectal tube; needle for hypodermoclysis and for intravenous injection of fluids or for spinal puncture; an aseptic glass syringe; a syringe for exploring purposes; a tube of smallpox vaccine; needles threaded with silkworm-gut and catgut in sealed glass tubes; a pair of rubber gloves and the following drugs: a bottle of bichlorid tablets, calomel and soda tablets, headache tablets, A. S. & B. pills, assayed Tr. digitalis, Tr. iodin, a tube of sterile petrolatum, 3 ounces of alcohol and two half-pound cans of ether. This physician also carried a hypodermic syringe and a case of tablets for hypodermic use, a clinical thermometer and a Bowles stethoscope.

It will be seen from the above equipment that about all that this doctor tried to do was to make a scientific diagnosis, and then ordered from the local drug store the medicine he thought his patient required. He does not claim that it is an ideal equipment, but it was evolved by twenty-five years of practice as that which best suited his particular needs. It is subject to change as need requires, and it suits him better than a bag full of tablets that he, at least, cannot use intelligently.—The *Medical Reporter* of the Chester County (Pa.) Medical Society.

Medicolegal

Not a Waiver of Privilege

(Nordyke & Marmon Co. vs. Whitehead (Ind.), 106 N. E. R. 867)

The Supreme Court of Indiana says that, in this action brought by an administratrix to recover for the death of an employee of the defendant company, the defendant contended that the court erred in sustaining the plaintiff's objection to certain questions propounded to the defendant's witness, a physician who attended the decedent immediately after his injury. A son of the decedent had testified that when the physician examined his father he (the witness) was present and saw certain bruised spots on his father's body. The defendant sought to prove by the physician that no bruises were found, and the court excluded the testimony on the ground that it was privileged. It was contended by the defendant that by offering the evidence of the son the plaintiff waived the privileged character of the physician's testimony as to the same subject-matter. The supreme court cannot so hold. The rule that all facts learned by a physician while examining or conversing with a patient are to be treated as confidential is a beneficent one and one which is not to be lightly broken down. The court sees no reason to hold that the circumstances before it were sufficient to bring this case within any recognized exception to the rule stated or to create a new exception thereto.

Negligent Care by Parents and Insanitary Condition of Home of Injured Child

(Gigoux vs. Yamhill County (Ore.), 144 Pac. R., 437)

The Supreme Court of Oregon affirms a judgment for $1,000 damages for the death of 10-year-old Emma Gigoux, who, on Sept. 21, 1912, stepped into a hole in a bridge, causing abrasions of the skin on both sides of the leg. The court says that she was taken home, a short distance from the place of the injury, the limb washed with soap and warm water, the wounds bathed with peroxid, a mixture of glycerin and phenol (carbolic acid) applied to the injured parts, and bandages placed thereon. The little girl was thereafter frequently bathed, clean clothing exchanged for that which had been worn, and the treatment referred to was repeated each morning for about ten days, when, incrustations having formed over the abrasions, it was supposed that the wounds were properly healing. In a few days, however, blood poison set in, whereupon physicians were called; but, they being unable to effect a cure, she died of septicemia on October 5. The defendant alleged, among other things, that there was only a slight scratch and during the first ten days or so Emma, with no proper treatment of the scratch, engaged in her usual play about the premises of her parents, permitting her clothing to rub and irritate the scratch and other articles to come into contact with it, and it to become unclean and filthy, and some ten days after the accident her limb became infected and sore, and same thereafter resulted in the ailment which caused her death. But there was no error in not permitting the defendant to offer testimony in support of the alleged insanitary condition of her home at the time of the accident and during her last illness. It was argued that the defendant's answer averred a new and intervening cause, but the court believes that the pleader, in the part of the defense referred to, intended to charge contributory negligence on the part of Emma's parents in failing to call a physician when she was hurt, in permitting her clothing to irritate the wounds, and in not exercising greater care in respect to the alleged insanitary conditions of the home, whereby the little girl's death resulted. As tending to uphold the latter view, counsel undertook to show that the girl's wounds might have been infected by germs when being bathed, by inquiring of Mrs. Gigoux, on cross-examination: "Did you ever boil the basin, or disinfect it in any way?" and, when an objection was sustained to the question, he said: "We are trying this case on the theory that the negligence of the parents would be an element." However, no error was committed in refusing to receive evidence of the alleged negligence of the girl's parents as to their care and treatment of her after she was injured. This action was brought by her father as the administrator of her estate.

Including the Element of Experience in Questions Asked Experts

(Chicago, I. & L. Ry. Co. vs. Gorman (Ind.), 106 N. E. R. 897)

The Appellate Court of Indiana, in affirming a judgment in favor of plaintiff Gorman for personal injuries, says that two physicians who had examined him several times after he had received the injuries, were called by him as expert medical witnesses. After they had respectively detailed the facts ascertained by such examinations, they were asked to give their professional opinions respecting the origin and nature of said injuries. Each question contained substantially the following: "From your examination of Mr. Gorman, . . . basing your answer on your experience as a medical man and the facts that you have detailed to this jury that you found existed," etc. Objection was made that the form of the question called into action the experience of the witnesses. But the court does not think there was error in that. As indicated, the witnesses were called and testified as experts. A question propounded to such an expert for the purpose of eliciting an opinion should be so framed as to require that such opinion be based on facts testified to by such witness, or on facts assumed hypothetically, or on both classes of facts. Here no facts were assumed hypothetically, and since each of the witnesses was required to base his opinion on facts testified to by him, it was conceded that the questions were correct in form, except it be on account of the element of experience, included therein. It was argued that such element in such questions brings them under the condemnation of the rule announced in Horne vs. Williams, 12 Ind. 324, to the effect that an expert medical witness may not give in evidence the particulars of his own private practice. The court does not so understand the questions here. Experience is a very potent factor in the process by which a person becomes an expert in any line. An expert, as the word implies, is one having experience. While, strictly speaking, it may be true that the word "experience" may mean the course or process by which one attains knowledge and wisdom, yet the former term is frequently used as the equivalent of the latter terms. The word "experience" implies skill, facility, or practical wisdom, gained by personal knowledge, feeling or action. The possession of practical wisdom is an essential in order that one may be an expert. The expert submits the facts in a particular case to the scrutiny of the wisdom so acquired, and thus he gives an opinion. Any reasonable construction of the questions under consideration leads to the conclusion that by the particular feature objected to the witnesses were called on to use that particular attribute without which they would not have been experts. The court did not err in overruling the objections to the questions.

Tennessee State Medical Association, Nashville, April 13-15.

CONFERENCE ON HEALTH LEGISLATION

Held in Chicago, Feb. 15, 1915

The Eleventh Annual Conference on Medical Legislation, under the auspices of the Council on Health and Public Instruction of the American Medical Association, was held February 15.

The chairman, DR. HENRY B. FAVILL, Chicago, said in part: The purposes of the administrative forces in this department of the American Medical Association can be summed up under the general idea of forming and molding public opinion. Public opinion with us, as in every great movement, must be regarded as fundamental. We have no authoritative American Medical Association policy. The Association has no hard-and-fast program. It is a mobile organization so far as concerns its definite achievements. Its relationship to the state organizations and to the public is one that is purely informal and advisory in character. Our own affairs, so far as they come within the range of effective activities, are of a very indefinite type. I say this the more forcibly because it is desirable at this time and at every time to emphasize the fact that the American Medical Association is not undertaking to dominate either its own membership or its public relationship. We have no desire or power to dictate anything in the way of strictly medical affairs or medicopublic affairs, and our position in the matter is and must continue to be strictly advisory. The question is, Why do we concern ourselves with the matter? And the answer is, Because there is a moral obligation on us to concern ourselves with the matter just to the extent that we are fit and equipped so to do. We have definite knowledge in some directions. We have mature, well-thought-out conceptions of our public relationships. We have a very clear understanding in many directions regarding public weal and public interest. So far as we have these conceptions more than people outside of the profession, so far are we under obligation to make effective what we know and believe. It is for this reason that we go on, under all sorts of discouragements, under all sorts of discrediting, trying, not to drive, but rather to lead the public to a strong, intelligent, cooperative action with us, looking to its own reconstruction on physical lines for its own protection.

Report of the Secretary

DR. FREDERICK R. GREEN, Chicago: The rapidly increasing public interest in health topics, the necessity of rational, practicable legislation for the protection of the public health, and the manifest importance of avoiding premature, immature and unwise legislative experiments in this field, all unite to emphasize the importance and the rapidly growing necessity of a more intelligent and scientific method of handling these subjects. The question which we must answer is whether or not the medical profession is qualified or will qualify to assume leadership in this field. If we cannot or will not, then we cannot complain if other forces take the lead which should belong to us. Competent leadership in any field involves two factors: first, accurate knowledge of the situation, and second, definite plans for its improvement. Let me particularly emphasize in this connection the necessity of physicians as a class recognizing the importance of medical sociology. The forty years which cover the development of modern medicine have been so crowded with efforts to increase our scientific knowledge that practically all of the attention and the best minds of the profession have been devoted to this portion of the field. In the old days when the practice of medicine was limited largely to the personal relations between physician and patient, the neglect of medical sociology involved no serious consequences. To-day, however, with the rapidly growing importance of the community and the diminishing importance of the individual, the necessity of careful, able, scientific study of this subject is becoming apparent.

The subjects for discussion at this conference are four in number, on each of which a bill has been drafted as a basis for discussion. Two of these are incidental and two are fundamental. These bills are not to be regarded as in any sense final or authoritative, but rather as suggestions and for criticism.

The report of the Committee on the Regulation of Medical Expert Testimony in insanity cases will show that the bill which will be presented is intended as a demonstration of a general bill which can be applied to other classes of cases.

The bill on the prevention of infant blindness was drafted by the old committee on this subject which preceded the Committee on Conservation of Vision. It will also be submitted for discussion and criticism.

Report of Committee on Medical Expert Testimony

Prof. E. R. Keedy, Northwestern University Law School, Chicago, presented the report of this committee, submitting an act providing a method for obtaining and presenting in court evidence regarding the insanity of the defendant in criminal cases.[1]

DISCUSSION

Dr. Harold N. Moyer, Chicago: This bill is more extensive in its applications and in what will prove to be its ultimate usefulness than a greater effort would have been to cover the field of expert testimony. As to the scope of the bill, it refers only to one narrow phase of expert medical testimony, namely, that which governs the admission of this testimony in criminal cases in which insanity is raised as a defense. I believe that narrowing of it is an exceedingly wise provision from a practical standpoint. There are two reasons why it should be limited. One is, it is easy to get such a bill enacted, whereas it would be practically impossible to get through any legislature a bill as broad as we could draw it. The other reason is that its practical application will aid in its passage. The bill establishes certain definite principles, and eventually, if this bill is adopted in any state, its usefulness, its simplicity, will lead step by step in its application to other fields of litigation.

Prof. E. R. Keedy, Chicago: This matter of expert medical testimony has not only been worked on by this committee of your Council, but by a larger committee of the American Institute of Criminal Law, of which two members of your committee, Dr. Moyer and myself, are members, so that in this bill we have presented the results of the labors of the two committees extending over a period of three years. The bill has already been presented to the American Institute of Criminal Law and unanimously approved by that body. After further consideration, we decided as a practical legislative matter that it would be wiser to confine the bill to insanity and testimony in criminal cases alone, and that is the form in which the bill has been presented to you. The only section of this bill as drawn regarding which we have any doubt as to its constitutionality is Section 2. Some states may hold that it is unconstitutional, although in other states it would be upheld as constitutional, as in Illinois. However, there is great difference of opinion, and that is one of the things which is being considered now by this committee and by members of the legislature who are going to handle the bill in the Illinois Legislature.

Dr. Victor C. Vaughan, Ann Arbor, Mich: Is it not true that in certain states Section 1 of this bill has been adopted and has been declared unconstitutional on the ground that it gives to the expert or experts appointed by the court too much authority? That was the case, if I am not mistaken, in Michigan.

Prof. E. R. Keedy, Chicago: Yes, in Michigan, and the statute was declared unconstitutional on two grounds, one of which was that it violated a clause in the constitution which states that court judges have no right to summon witnesses at common law, as it would give those summoned by the court prestige over those summoned by the parties involved. The other ground on which the statute was held unconstitutional was that it failed to provide the giving of notice to the council for both sides that such witnesses had been appointed.

Dr. S. L. Jepson, Wheeling, W. Va.: Is it not true that, according to Section 1 of this bill, the court is under obligation to award fees to experts?

Prof. E. R. Keedy, Chicago: That is true. This bill says that "the witnesses summoned by the judge shall be allowed such fees as in the discretion of the judge seem just and reasonable, having regard to the services performed by the witnesses." While that is not satisfactory for the purpose of securing the best witnesses, we know as a fact that experts who are summoned by the parties involved receive more than ordinary witness fees, so unless there was such a provision, the court would not award the fee. There are provisions for the compensation of witnesses to be fixed by the court and payable out of the county or state treasury, and no question has been raised as to the constitutionality of such sections.

Dr. Victor C. Vaughan, Ann Arbor, Mich.: This law was in effect in Michigan from 1905 up to 1909, and we boasted that we were the only state in the Union that had a decent law concerning expert testimony. Both doctors and lawyers were well pleased with the law. I gave expert testimony a great many times under the law, and the whole atmosphere of the courtroom was different from what it was in other states at that time where I also gave testimony, and so we were proud of Michigan. When the Supreme Court declared it unconstitutional, that decision met the disapproval of doctors and lawyers, and so even in Michigan there is room for improvement in supreme courts.

Prof. E. R. Keedy, Chicago: The only instance wherein a definite proposition was made was in Massachusetts. A bill was introduced into the legislature there which provided for and stipulated exactly what the requirements of an alienist should be. He should be a graduate of a recognized medical school, according to the State Board of Examiners in that state, and he should have so many years of clinical experience and so many years connection with a hospital. That bill failed to pass, and I think it would have been unwise to pass it. Your committee felt helpless in the matter of proposing a test. There are certain powers given the court in this matter, and although the jury may pass on the credibility of witnesses, the question of qualification itself lies in the hands of the court.

Judge Albert C. Barnes, Chicago: This bill brings the two professions together on common ground. We recognize that the complaint has been made for a long time that in the presentation of a case in court there is very little opportunity for the expression of medical theory. Perhaps the medical profession has lost sight of a very important fact, that the alienist is not consulted in court as a family physician. If members of a family are desirous of ascertaining the mental condition of a certain member of that family, they consult an alienist, and not a jury. In the trial of cases the determination of the final fact is left to the jury, and is not to be determined by the opinions of the medical profession. Therefore, they have to have a standard or a test by which sanity or responsibility may be determined. The complaint of the medical profession has been that they are not concerned with definitions, but only with conditions and methods of treatment. But we have to have a standard in the courts by which a jury may be guided, and that standard in this state and most states is a very simple one. It is whether or not at the time of the act the individual knew whether it was wrong, and whether he had the ability to choose to do the act or not and of controlling his conduct in accordance with that choice. That ought to be a fair enough test to apply to anybody wandering around the streets or in society. Alienists can be expected to testify only on a subject which has many elements of uncertainty; but when actions are so frequent, especially those of prominent and wealthy citizens, there are calls for the talent of alienists. I recognize that we may expect a disagreement among alienists from the very nature of the subject, but one would be almost led to believe from practical experience in courts that either the subject was beyond the pale of scientific knowledge and lay in the realm of speculation, or those professing to have knowledge of it are not always honest and sincere in their opinion. I would not cast the blame for this situation alone on the medical profession. The lawyer is senior partner in that abuse. He is the real instigator of it. He needs a defense, and in the language of the day, he needs it bad. He needs that situation usually in that class of cases in which the defense of insanity is a great mask for an appeal to the unwritten law. Far better would it be for the law to recognize a defense of that character than that eminent members of the legal and medical professions should have engaged in a conspiracy against the truth. As to the provision in this act which provides for calling into the case disinterested witnesses, I cannot agree that it will in no way interfere with experts. I think it will; not real experts, but men who profess to be experts will hardly dare come into the case for a reward and subject themselves to the criticism of opposing and disinterested opinions that will be called into the case under the provisions of this bill. There lies a great evil, and this bill is to my mind well calculated to remove it.

---

[1] Copies of the bills discussed can be secured from the Council on Health and Public Instruction, American Medical Association, 535 North Dearborn Street, Chicago.

I congratulate both your profession and mine that we are able at last to meet on something like common ground in regard to this important subject, and while this bill may not be perfect, it is well to set it on its way, so that it may receive such criticism and pruning as it will when it passes through legislative hands and the judgment of courts.

Dr. Victor C. Vaughan, Ann Arbor, Mich.: While this is the best we can probably do under the circumstances, how ridiculous it is to put up the question, Is this man insane? to twelve ignorant men. I do not care who testifies, good or bad men, or who pleads, good or bad men. The time must come when all cases of this kind will be tried before a bench of experts, men who are learned in the law and those who are learned in psychology, and they shall diagnose the case and prescribe treatment. I have no hesitancy in saying, after being an expert witness in many of the states of the Union, that in murder cases, whether the claim be insanity, whether it be poisoning, or whatever it may be, the jury system is an absolute failure. No honest man respects it; no rogue fears it. The time will come when all criminal cases will be tried by a bench of expert psychologists who will be both lawyers and doctors. What the legal and medical professions should strive for is not so much to reform the criminal as to stop his breeding. He is not the product of civilization; he is the excrement of civilization, and should be treated accordingly. I do not mean to say that we should hang him or torture him, or anything of that kind, but we should place him where he can no longer feed on the community or reproduce his kind.

Dr. W. L. Beebe, St. Cloud, Minn., moved that the conference approve the bills presented by the Committee on Expert Testimony and recommend their enactment by the legislatures of the various states, which motion was seconded and carried unanimously.

Prevention of Blindness

The secretary presented the draft of a bill for the prevention of blindness from ophthalmia neonatorum, defining ophthalmia neonatorum, designating certain powers and duties, and otherwise providing for the enforcement of the act.

DISCUSSION

Prof. Albion W. Small, University of Chicago: My message to the medical profession is this: In undertaking to put your knowledge of medical cause and effect at the service of your fellow citizens, you are not simply doing that service in this particular matter of medical, sanitary and hygienic legislation, but you are using that as an illustration to teach Americans lessons they need. We need to learn how from those who are competent to teach us in matters which require expert judgment. I hope you will appreciate, therefore, my desire to applaud you as American citizens for your services, not merely as medical men, but as patriotic citizens in pointing to high standards for our American conduct.

Dr. Frank Allport, Chicago: There are at the present time in the United States about 20,000 blind persons who have been made blind by ophthalmia neonatorum. There are twelve states in the Union that have laws on the subject of ophthalmia neonatorum. One of the objects in framing this bill is to have it uniform. In other matters and in other affairs, conditions are different in different states, and what might be applicable in one state would not be applicable in another; but here is a matter that should and must be the same in all states. We ought not to have in such a matter as this individual laws for individual states, but a uniform law for all states.

The use of nitrate of silver in the eyes, according to the method proposed by Credé, has reduced the occurrence of ophthalmia neonatorum from 10 per cent. in the new-born child to 1 per cent. This is a good bill. It should be passed, and I hope the members of this conference will not only recommend but assist in the passage of this bill in the various states.

Dr. George B. Young, Health Commissioner of Chicago: I would like to raise a point in regard to one section of this bill: While I am heartily in sympathy with the purpose of the bill, I question the expediency of the language used on account of the fact that it divides responsibility practically between everybody resident in the house in which a child happens to be born. What we want done in this matter is to narrow down the responsibility to the very narrowest limits, to put it definitely on the physician, midwife or other person immediately in charge of the infant at the time of birth or immediately after birth. If that is not done, you cannot successfully maintain prosecution.

Dr. Henry M. Bracken, St. Paul: All communicable diseases are controlled in Minnesota by regulations of the State Board of Health. We have regulations relating to ophthalmia neonatorum, but they are not enforced because doctors need educating. It is the doctors who are at fault, and we cannot get anything done until not only the doctors themselves get busy, but the medical schools educate the students that are to practice medicine in regard to the importance of this matter.

Dr. Rachelle S. Yarros, Chicago: The suggestion made by Dr. Young of not dividing responsibility too much is excellent. In some cases, if the provisions mentioned in this bill were carried out, the neighbors who come to see the child immediately after birth would be likewise held responsible for not reporting ophthalmia neonatorum. One important thing that should be brought out clearly in such a bill is that ophthalmia neonatorum is due to gonorrhea in many, many instances; also the importance of the use of the Credé solution should be emphasized.

Dr. Frank Allport, Chicago: As to the remarks of Dr. Yarros, it has been the intention of those who are endeavoring to regulate this matter to make the people understand that all cases of sore eyes in babies or ophthalmia neonatorum are not due to gonorrhea. One reason why we have difficulty in getting cases reported is because the impression is abroad in the land that all of these cases are due to gonorrhea, and therefore people regard it as a social and family shame and mortification to report cases of this kind because it is an open admission there is gonorrhea in the family.

State Regulation of Public Health

Dr. Henry M. Bracken, St. Paul: In considering this problem, we should first discuss the methods that have been in vogue. These may be grouped in a general way under three heads:

1. The board which has to do purely with public health matters.
2. The state health commissioner, acting alone or with the board that has practically no responsibility.
3. The board which has charge not only of public health matters but also of the licensing of physicians.

I think it is now conceded that none of these are ideal, and that the third should in no instance be tolerated in future legislation relative to public health.

The first thing to consider in the organization of a state health department is efficiency. This can be secured only by insuring permanency in position for those engaged in the various lines of public health work. Permanency in position can be secured only by the removal of public health activities from political control.

After presenting forms of state health organization in several states and pointing out their weak and strong points, Dr. Bracken said: An ideal organization for state health activities might be somewhat as follows:

Department of Health, consisting of:

1. Public health council.
2. Commissioner of health.
3. Bureaus.
4. Divisions, if necessary.

The council might consist of five members appointed by the governor for five years, one appointment to expire each year. Such council should have authority to make rules and regulations relative to public health. There should be a penalty for failure to comply with such regulations. The council should also have authority to appoint the commissioner of health.

The commissioner of health might well be vested with the authority similar to that now given in New York state.

To aid the commissioner in carrying out his work there should be subdivisions designated as bureaus rather than as divisions. The bureau work could then be subdivided into divisions, if necessary.

If necessary, for lack of other suitable place, to add other responsibilities to a health department than those strictly belonging to it, such as the supervision of food products, labor problems, or examining boards, these could be arranged for under bureaus or divisions, as might be deemed necessary.

The secretary presented a short law creating a state board of health, approved by the Council on Health and Public Instruction; and also a bill drafted by the Medicolegal Bureau as a basis for discussion, but not yet submitted to the Council, which provides for the regulation and supervision of all persons who treat any sickness, injury, etc., of any human being for compensation within the jurisdiction of any state.

He said these were tentative bills and are not to be regarded in any way as finished products, but are submitted as a basis for discussion.

Dr. Henry B. Favill, Chicago: We can only get ahead in this matter by a consensus of opinion, or as nearly a consensus of opinion as may be, and out of these reports and discussions there may come some light for the administrative forces of the Council toward a more formal draft of such bills.

Dr. George B. Young, Chicago: As this discussion is thrown open to a general consideration of the question of public health organization in the states, I think we have to get back to certain first principles. The first thing we run up against is the growing development of the social consciousness of the people of the United States, as expressed in their reaching out and attempting to establish organizations having as the title the attractive name of "public welfare." I am one of those who believe that the public health work of the future, and the public health work of the present, have already taken the shape in which the basal developments are sociologic and not medical. The medical profession must supply men who are not only in a position to handle medical but sociologic side of questions as well —men equipped to handle all the questions which concern public welfare, or its representatives will be relegated to second place. In any organization of this kind which we are coming to, the health department must either swallow the welfare department or the welfare department must swallow the health department. As long as public health work in states or municipalities is confined to looking after the control of communicable diseases and of educating the people for the purpose of limiting the death rate from such diseases, and such related questions as sanitary engineering, which has to do with the water supply, etc., we are bound to be left behind, because the governmental agencies in this country are developing very rapidly along such lines as industrial accidents, industrial safety, occupational diseases, and the care of the child. I do not mean simply infant welfare work, or the child as a general proposition, but housing, and everything of that kind, is going on faster because it is a more popular field. It is the thing of the hour; therefore, it is going on more rapidly than public health development, even as rapidly as that is going on. We have to recognize that situation and proceed accordingly.

I want to put myself on record as believing that what we want is a single-headed health department in the state, with an advisory council, for the purpose of drafting rules and regulations susceptible of immediate interpretation and immediate enforcement as general statutory requirements passed by the legislature.

Prof. Charles R. Henderson, University of Chicago: I have read carefully the draft of the bill which is before you, and I am exceedingly delighted with the fundamental idea in it. I want to point out how exceedingly important the principles contained in this bill are in other matters. When we are trying to improve public service in any line we have the choice of having factional partisan politics to determine for us, or accept the principle which is at the basis of the bill offered here. Men who are learned in medical science should not only be the advisers but they should be in control. For the first time in the history of the world in the Panama zone and in some other parts of the world medical men have not only had advisory power, but administrative power, and we see what splendid results they have given forth, developing not only great medical skill but a very high degree of administrative skill.

I congratulate you on the formulation of this bill. It seems sensible. It may need some revision at the hands of lawyers or doctors, but it points in the right direction, and I believe your meeting here will be a great blessing for our citizens and help to mark some steps forward in the great way to progress.

Dr. H. B. Hemenway, Evanston, Ill.: I want to protest against the board idea in public health work. When the United States Constitution was formed, the framers of it considered the matter of multiple executives and decided against it, and with good reasons, as set forth by Justice Storey, namely, that when you have multiplicity in executives you have lack of efficiency, you have slowness of action, and you have no responsibility. Responsibility is so divided you can never find it; consequently a board of health, strictly speaking, has no legislative authority.

Dr. John A. Robison, Chicago, outlined a proposed bill that the Illinois Efficiency and Economy Committee proposes to introduce into the legislature, and explained the different sections of it.

Dr. R. W. Corwin, Pueblo, Colo.: The greatest obstacle we have to meet in public health matters is the proper enforcement of our laws. What is to be done to improve conditions? Educate the people. How can we teach the people? Until they are taught and understand and learn the importance of carrying out laws, they will not and cannot be expected to obey. For some years I have been engaged in this work, and I find we must educate the people before we can expect them to comply with our requests.

Dr. Walter L. Bierring, Des Moines, Iowa: The Iowa organization of the board of health, which is similar to the one that has been proposed to-day, has been in force for two years, and the governor in his inaugural message referred to it as the most efficient in the history of the state.

Dr. J. M. Baldy, Philadelphia: In administering your law put it up to the people. If they see it is not for your own benefit, they will accept it, and the fact that it is put up to them will educate them. Instead of wasting your energy on getting new laws, put your energies into getting administrators with courage and backbone who will administer the laws.

Dr. R. O. Beard, Minneapolis: Medical men have been the directors of public health work in the past because they were the only men who knew anything about public health matters; but the time has come when other people than the men of medicine know a great deal about public health matters, and public health has become a sociologic and economic problem as well as medical problem.

Dr. C. E. Cantrell, Greeneville, Tex.: I think the people of the different states of the Union are pretty well of one mind, namely, they need an executive head to a health department, and that executive head needs an advisory board. We have that down in Texas, and we put everything on the statute books that we can agree on.

Dr. Henry M. Bracken, St. Paul: I am pleased with the opposition taken by Dr. Young relative to public welfare. Some of us have been preaching that doctrine for a long time. It is hard to get in touch with people outside of the medical profession. I hope there will be a possibility for health workers to get in closer touch with economists.

Dr. Henry B. Favill, Chicago: It is a great disappointment to the conference to chronicle the absence of Hon. G. H. Hodges, governor of Kansas, who was to have read a paper entitled "State Regulation of Those Who Treat The Sick."

In the absence of Governor Hodges, I will ask the secretary of Council, Dr. Green, to introduce the subject.

Dr. Frederick R. Green, Chicago: I have not the slightest hope or intention of filling the place of Governor Hodges in presenting this subject, but desire to call your attention to a tentative bill which you will find under the head of "State Regulation of Those Who Treat The Sick."

There is an earnest desire on the part of the Council and Medicolegal Bureau to get a definite discussion and a concentrated idea in regard to the best method of handling the extremely difficult and complex problems that come up under the general question of the licensing of persons who are to treat the sick or to practice medicine under the various sects.

Dr. Green then gave a brief outline of the history and development of this movement, emphasizing the fact that the entire question was an educational and not a sectarian one and that the only fair basis was a single standard for all.

Dr. Charles H. Cook, Natick, Mass., President of the Federation of State Examining and Licensing Boards: I do not feel that I have had sufficient concrete experience to discuss this subject intelligently, and when I realize that we have with us the executive officers of several state boards who have had actual experience in the courts and elsewhere bearing on the conditions set forth in the bill, I feel they have a right to be heard first, and I shall avail myself of a new beautitude of James Russell Lowell, "Blessed are they who have nothing to say and cannot be persuaded to say it." That is my position in regard to talking about the details of this bill. However, we are getting beyond the first stage principle in the different steps of reform laid down years ago by William Lloyd Garrison, the great antislavery agitator, when he said (I cannot quote his exact words): Talking creates zeal; zeal creates inquiry; inquiry creates opposition; opposition creates action; action creates union, and union creates victory.

Dr. Arthur Dean Bevan, Chicago: I believe the time has distinctly come when the profession and the people of this country recognize the fact that medicine is to-day a science just as much as chemistry is. Feeling as I do about this matter, the practical and clear proposition that confronts us is that we should attempt to obtain public opinion that will enable us to have in our state governments some means by which we can determine whether or not a man or woman is a well-qualified practitioner of scientific medicine; that we should have some way in our state governments of not only determining that point, but designating whether that individual is a competent practitioner of medicine. I do not think anything else is necessary.

Dr. C. N. Suttner, Walla Walla, Wash.: Our state board of examiners is pursuing a relentless warfare against quacks, particularly so-called chiropractics. We have convicted forty-three. We have no legal right to limit applicants that come before the board, but we have assumed the right that a young graduate must have certain qualifications.

Dr. George B. Young, Chicago: We have been trying for many years—and no one more efficiently than Dr. Bevan and his colaborers—to raise the standard of medical education in the United States, and we have sought to do that in part by imposing on the candidate for medical education a constantly rising standard of preliminary education. What we have done really is this: We have made rules of practice in the medical schools which require a candidate to have the equivalent of a high school education of two years of preliminary work in biology and other branches, but we have no machinery by which we can tell whether or not the medical schools are really doing the thing which they are supposed to do.

Dr. William A. Stewart, Pittsburgh: If we are to regulate the practice of medicine and eliminate quacks, it should be done in one way, and that is to have a uniform standard of education.

Dr. William H. Welch, Baltimore: I am in sympathy with the position of Dr. Bevan. We are not the allopathic school; we are not a school of practice but are simply physicians, and there is no method of treatment of a patient—osteopathic, homeopathic or Christian Science—that a member of our profession is not at liberty to use if he thinks it will benefit the patient. There are two principles which have always guided the regulation of medical practice. One is an effort on the part of the state to secure a body of scientifically trained physicians, and the other is an effort to eliminate quacks.

Dr. J. M. Baldy, Philadelphia: I have a strong basic belief that the way to wipe out quackism is to put the quack in such a dignified position that he will no longer be a quack, as he himself will get what good he can and see what merit there is in what he is doing, and he will gradually himself wipe out that which he sees himself, as he becomes more educated, is pure quackery. In that way there will be created an enormous impetus which will go toward wiping out quackism. With that as a basis, there is absolutely no justification whatever for any medical man to believe, ask or think that there should be any legislation given for his protection.

Dr. B. D. Harison, Detroit: We have the condition that Dr. Baldy is contending for in Michigan. We license drugless healers, but they must have a preliminary education sufficient to study medicine and also possess a fundamental education in order to make a good diagnosis.

Dr. Otto V. Huffman, Albany, N. Y.: In New York the matter under discussion has been worked out on the basis of educational qualifications. In 1889 the Board of Regents began to require a medical student's certificate. At that time there were three separate medical examining boards—eclectic, homeopathic and the Medical Society of the State of New York. All the applicants for admission to any of these state boards had to have the same preliminary education as far as minimum requirements were concerned. In 1907 the State Board of Medical Examiners was created, and under the law there is no recognition given to any sect. The only way in which any recognition is given to a sect is this: Osteopaths are required to have the same preliminary education as others. They have to attend a professional school the same length of time and pass the same state board examination.

The subject was further discussed by Dr. Thomas F. Duhigg, Des Moines, Iowa; Dr. E. T. Abrams, Dollar Bay, Mich.; Dr. E. W. Warren, Palatka, Fla., and Dr. George H. Matson, Columbus, Ohio, after which the conference adjourned.

6 *Voice Sign in Chorea—Technic of Elicitation. W. B. Swift, Boston.

3. **Energy Metabolism.**—Ten infants ranging in age from 2 months to 12 months and in nutritive condition from the last stage of marasmus to considerably overweight, were compared by Murlin and Hoobler as to their heat production both on the basis of weight and of surface area. The heat production was calculated from the oxygen absorption with knowledge of the respiratory quotient (corrections being made for temperature, barometric pressure, and composition of the air) and from the nitrogen of the urine. Graphic records of the respiration (in all cases) and of the pulse (in all but three cases) were obtained, these recording devices serving also to exhibit plainly on a smoked paper the degree of quiescence of the subject. The approximate specific gravity was determined by Kastner's method in the hope that it might serve as a measure of the proportion of fat to active tissue. The child was fed immediately before the observation each day and in nearly every experiment slept at least one, often two hours, while the respiratory exchange was being measured.

The authors found that the heat production for the sleeping period averages for the ten children 2.7 calories per kilogram and hour. It is highest on this basis for the atrophic and underweight children and lowest for the fattest child. On the basis of a square meter of surface the heat production of normal children shows a decided increase from the early months (2 to 4) to the later months (6 to 12) of the first year. The average of all the ten children is 39.7 calories. The average deviation from the mean heat production in all sleeping periods is about ± 10 per cent. for each of the several formulas expressing the relation of surface area to weight. Almost identically the same average heat production per unit of weight and per unit of surface is obtained when the infants between 2 months and 12 months (sixty-one in all) are compared, namely, 2.7 calories per kilo and hour, 39.3 calories per square meter and hour (Meeh). On the unit of weight all but three of the atrophic and underweight children (forty-eight in all) lie above the line represented by 2.5 calories per kilogram and hour; all the normals (eighteen) lie near this line; and all but one of the overweight infants (five) lie below this line. Two and one-half calories per kilogram and hour or 60 calories per kilogram and twenty-four hours may therefore be called tentatively the "normal heat production" of recently fed, sleeping infants between 2 months and 1 year of age. Included in this figure is whatever dynamic action the foods themselves may have; otherwise the figure is minimal. Hard crying may increase the metabolism as much as 40 per cent.; the requirement for growth and an allowance for non-absorption must be added. The average deviation from the mean on the basis of weight for all these children is 12.1 per cent.; on the basis of surface area (Meeh) 11 per cent. For smaller age groups of normal children the deviation is considerably less on the basis of surface area than on the basis of weight.

4. **Whey in Infant Feeding.**—The authors confirm the work of Osborne and Mendel in which they demonstrated the necessity of whey salts to promote growth of the young when fed on pure materials—fats, carbohydrates and protein. The investigation also seems to bear out the theory that creatin excretion is in some way involved in growth and also to offer an explanation of the fact observed by others that the creatin excretion of growing infants varies from day to day.

6. **Voice Sign in Chorea.**—The technic for eliciting the voice sign in chorea is to request the patient to sound a prolonged "a" as in "are" and to watch for the changes in vocal pitch and intensity which constitute the sign. If a contraction occurs in the expiratory muscles, the sound will markedly change in intensity and for the rest of the utterance, or until the occurrence of another contraction, the sound will return to its previous evenness of utterance. If during the sounding of "a" there occurs a choreic contraction in or near the vocal cords so that they are made more tense, the tone of that sound of "a" is thereby raised in pitch and then resumed at its previous level. The typical choreic voice sign is a change in pitch and intensity.

January, XXXII, No. 1, pp. 1-80

7 Precocious Maturity in Girls. Report of Case. F. Beekman, New York.
8 *Cutaneous Tuberculin Test in Children of Non-Tuberculous Parentage. M. Fishberg, New York.
9 *Streptococcus Meningitis. Report of Cured Case (Serum). P. L. Du Bois and J. B. Neal, Brooklyn.
10 Management of Breast Feeding. F. Vander Bogert, Schenectady.
11 Importance of Medical Supervision of Older Children. E. J. Wynkoop, Syracuse.

8. **Cutaneous Tuberculin Test in Children.**—Among 588 apparently healthy children of non-tuberculous parentage, Fishberg says, 52.72 per cent. gave positive reactions to tuberculin. During the first year of life the proportion of "reactors" is small and insignificant. From 1 to 2 years of age, 33.33 per cent. reacted; between 3 and 4 years of age, 41 per cent.; between 5 and 6, 50 per cent.; between 7 and 10, 64.74 per cent.; between 11 and 14, 69.4 per cent.; and at 14 years of age, 75 per cent. showed evidences of having been infected with tubercle bacilli. It appears that the cutaneous tuberculin test is quite reliable in showing whether or not a person has been infected with tubercle bacilli. It is, however, of little value in the diagnosis of the disease known as tuberculosis in its various manifestations. It appears that in large cities like New York, and even in small rural communities, most of the children have been infected with tubercle bacilli before reaching adolescence, though they have not necessarily suffered as a result of this infection.

9. **Streptococcus Meningitis.**—During the past four years Du Bois and Neal have seen eighteen cases of streptococcic meningitis, of which only one recovered. Five of these were due to *Streptococcus mucosus capsulatus*—considered by most as belonging to the pneumococcus group, the rest to the *Streptococcus pyogenes* group. In 2 of the cases the histories were lost. Of the remaining 16 there was no history obtainable bearing on the condition in 5 cases; 5 cases gave a previous history of middle-ear disease or mastoid; 2, of scarlet fever, middle ear and mastoid; 1, of operation on the nose; 2, of trauma of the head; 1, whooping-cough. Of these cases 7 received antistreptococcus serum, 5 receiving more than one dose intraspinally, intravenously or both. One of these recovered, as reported, and the other 4 showed considerable temporary improvement, though 3 were seen six days or more after the onset of symptoms. The fluids, too, showed improvement, the organisms becoming more and more intracellular and in one case diminishing in numbers.

12 Stricture of Esophagus. A. G. Schnabel, Tucson.
13 Artificial Pneumothorax. W. W. Watkins, Phoenix.
14 Vital Statistics in Arizona. J. W. Flinn, Prescott.

Dr. J. M. Baldy, Philadelphia: In administering your law put it up to the people. If they see it is not for your own benefit, they will accept it, and the fact that it is put up to them will educate them. Instead of wasting your energy on getting new laws, put your energies into getting administrators with courage and backbone who will administer the laws.

Dr. R. O. Beard, Minneapolis: Medical men have been the directors of public health work in the past because they were the only men who knew anything about public health matters; but the time has come when other people than the men of medicine know a great deal about public health matters, and public health has become a sociologic and economic problem as well as medical problem.

Dr. C. E. Cantrell, Greeneville, Tex.: I think the people of the different states of the Union are pretty well of one mind, namely, they need an executive head to a health department, and that executive head needs an advisory board. We have that down in Texas, and we put everything on the statute books that we can agree on.

Dr. Henry M. Bracken, St. Paul: I am pleased with the opposition taken by Dr. Young relative to public welfare. Some of us have been preaching that doctrine for a long time. It is hard to get in touch with people outside of the medical profession. I hope there will be a possibility for health workers to get in closer touch with economists.

Dr. Henry B. Favill, Chicago: It is a great disappointment to the conference to chronicle the absence of Hon. G. H. Hodges, governor of Kansas, who was to have read a paper entitled "State Regulation of Those Who Treat The Sick."

In the absence of Governor Hodges, I will ask the secretary of Council, Dr. Green, to introduce the subject.

Dr. Frederick R. Green, Chicago: I have not the slightest hope or intention of filling the place of Governor Hodges in presenting this subject, but desire to call your attention to a tentative bill which you will find under the head of "State Regulation of Those Who Treat The Sick."

There is an earnest desire on the part of the Council and Medicolegal Bureau to get a definite discussion and a concentrated idea in regard to the best method of handling the extremely difficult and complex problems that come up under the general question of the licensing of persons who are to treat the sick or to practice medicine under the various sects.

Dr. Green then gave a brief outline of the history and development of this movement, emphasizing the fact that the entire question was an educational and not a sectarian one and that the only fair basis was a single standard for all.

Dr. Charles H. Cook, Natick, Mass., President of the Federation of State Examining and Licensing Boards: I do not feel that I have had sufficient concrete experience to discuss this subject intelligently, and when I realize that we have with us the executive officers of several state boards who have had actual experience in the courts and elsewhere bearing on the conditions set forth in the bill, I feel they have a right to be heard first, and I shall avail myself of a new beautitude of James Russell Lowell, "Blessed are they who have nothing to say and cannot be persuaded to say it." That is my position in regard to talking about the details of this bill. However, we are getting beyond the first stage principle in the different steps of reform laid down years ago by William Lloyd Garrison, the great antislavery agitator, when he said (I cannot quote his exact words): Talking creates zeal; zeal creates inquiry; inquiry creates opposition; opposition creates action; action creates union, and union creates victory.

Dr. Arthur Dean Bevan, Chicago: I believe the time has distinctly come when the profession and the people of this country recognize the fact that medicine is to-day a science just as much as chemistry is. Feeling as I do about this matter, the practical and clear proposition that confronts us is that we should attempt to obtain public opinion that will enable us to have in our state governments some means by which we can determine whether or not a man or woman is a well-qualified practitioner of scientific medicine; that we should have some way in our state governments of not only determining that point, but designating whether that individual is a competent practitioner of medicine. I do not think anything else is necessary.

Dr. C. N. Suttner, Walla Walla, Wash.: Our state board of examiners is pursuing a relentless warfare against quacks, particularly so-called chiropractics. We have convicted forty-three. We have no legal right to limit applicants that come before the board, but we have assumed the right that a young graduate must have certain qualifications.

Dr. George B. Young, Chicago: We have been trying for many years—and no one more efficiently than Dr. Bevan and his colaborers—to raise the standard of medical education in the United States, and we have sought to do that in part by imposing on the candidate for medical education a constantly rising standard of preliminary education. What we have done really is this: We have made rules of practice in the medical schools which require a candidate to have the equivalent of a high school education of two years of preliminary work in biology and other branches, but we have no machinery by which we can tell whether or not the medical schools are really doing the thing which they are supposed to do.

Dr. William A. Stewart, Pittsburgh: If we are to regulate the practice of medicine and eliminate quacks, it should be done in one way, and that is to have a uniform standard of education.

Dr. William H. Welch, Baltimore: I am in sympathy with the position of Dr. Bevan. We are not the allopathic school; we are not a school of practice but are simply physicians, and there is no method of treatment of a patient—osteopathic, homeopathic or Christian Science—that a member of our profession is not at liberty to use if he thinks it will benefit the patient. There are two principles which have always guided the regulation of medical practice. One is an effort on the part of the state to secure a body of scientifically trained physicians, and the other is an effort to eliminate quacks.

Dr. J. M. Baldy, Philadelphia: I have a strong basic belief that the way to wipe out quackism is to put the quack in such a dignified position that he will no longer be a quack, as he himself will get what good he can and see what merit there is in what he is doing, and he will gradually himself wipe out that which he sees himself, as he becomes more educated, is pure quackery. In that way there will be created an enormous impetus which will go toward wiping out quackism. With that as a basis, there is absolutely no justification whatever for any medical man to believe, ask or think that there should be any legislation given for his protection.

Dr. B. D. Harison, Detroit: We have the condition that Dr. Baldy is contending for in Michigan. We license drugless healers, but they must have a preliminary education sufficient to study medicine and also possess a fundamental education in order to make a good diagnosis.

Dr. Otto V. Huffman, Albany, N. Y.: In New York the matter under discussion has been worked out on the basis of educational qualifications. In 1889 the Board of Regents began to require a medical student's certificate. At that time there were three separate medical examining boards—eclectic, homeopathic and the Medical Society of the State of New York. 20. **Skin Test in Typhoid.**—In order to compare the skin reaction with the Widal test for agglutinins, all patients suffering from typhoid admitted to the Sacramento County Hospital during the past summer received a skin test at the same time the blood for Widal test was made. At first Gundrum used a suspension of dead bacilli, 100 million to 1 c.c., *obtained from one of the commercial houses.* One-tenth c.c. (0.1 c.c.) of this bacterin was injected intradermally usually leaving a wheal about 5 or 6 mm. in diameter. If a red maculopapule as large or larger than the original wheal appeared between six and forty-eight hours from the time of injection, he considered the test positive. Gundrum tried this suspension of dead bacilli on eleven patients, six typhoids with positive Widals and five non-typhoids. In no case did a satisfactory reaction develop. Then he substituted Gay's vaccine, a suspension of sensitized and ground up typhoid bacilli of greater bacterial density (750 million to 1 c.c.). On thirteen typhoid patients this suspension gave a distinct positive in ten. Ten also gave a positive Widal test, but not the same ten. Of nine malaria patients eight did not give a reaction. Of eight controls none reacted. Thus the suspension of sensitized ground bacilli introduced intradermally gave reactions in as many patients as agglutination was observed in the Widal test, while the ordinary suspension failed to produce a characteristic response.

27. **Treatment for Typhoid.**—Knowing the efficacy of the bacillus bulgaricus in colitis colica and the summer diarrheas of both infants and adults Collings began using it some time ago in the treatment of typhoid and the results are very encouraging. By thoroughly saturating the patient with the culture of bacillus bulgaricus Collings states that the normal alkaline state of the bowel is changed to an acid one and inhibits further growth of the ingested typhoid bacilli (if not killing them), thus reducing the severity of the attack in all its symptoms excepting the persistent headache, and avoids the (1) initial constipation with following diarrhea, (2) extreme prostration, (3) dangerous tympanites, and (4) delirium. The usual emaciation does not follow, for it is not necessary, after saturation, to keep them on a liquid diet; a small dose of castor oil promptly relieves any discomfort. The usual supporting remedies are required.

45. **Research Demonstrating Infectious Nature of Cancer.**—His experience with cancer has forced Abelmann to look on "carcinoma" and "sarcoma" as different manifestations of the same disease and to regard cancer as truly an infectious disease as tuberculosis and syphilis. He says that there is a difference between cancer cell transplantation and cancer infection. (*a*) With the transplantation of a malignant tumor the cells simply continue their growth as a piece of the original tumor. With cancer infection, however, the specific microorganism is responsible for the development of cancer and here the infected animal's own tissue cell undergoes a malignant change. (*b*) In inoculating with the cancer germ any type of this disease is liable to develop.

Whereas with a transplanted cancer the same type of tumor will develop as has been transplanted. (*c*) In infected animals there is no telling where a tumor will develop. With transplanted cancer, however, a tumor will grow at the site at which the grafting was performed. (*d*) With cancer infection, animals will take the disease irrespective of species, whereas with cancer cell transplantation animals of the same or closely allied species have shown results. (*e*) With cancer infection usually metastatic tumors develop, whereas with cell transplantation secondary growths very rarely occur. (*f*) Time is a great and important factor with infection, as manifestations of the disease appear months and even years after inoculation (henceforth the impossibility of diagnosing cancer in its early stage in human beings). Whereas with transplanted cancer a tumor usually starts to grow as soon as it is grafted. Certain infected animals never developed cancerous tumors (carcinoma and sarcoma), but developed conditions that strongly suggest the probable similarity or possible identity of conditions found in human beings, namely, pernicious anemia and leukemia; others die from a condition simulating tuberculosis.

46. **Diagnostic Worth of Laboratory Data in Gastric Cancer.**—In 18 per cent. of 700 cases studied by Smithies the removed material or the vomitus was dark brown or coffee colored. Many extracts were cream colored, dark green, yellow or bright red. In cases in which coffee-colored contents were noted, there was in 96 per cent. a hopelessly extensive process. In 65 per cent. the vomitus of test-meal extracts were rancidly sour. Twelve-hour retention was demonstrated in 504, or 72 per cent. In but 54 per cent. was free hydrochloric acid absent. In nearly 46 per cent. free Hcl ranged from a trace to as high as 120. One out of every five patients had free Hcl between 20 and 50.

Total acidity ranged above 50 in about 20 per cent. and combined acid and acid salts were below 50 in nearly 90 per cent.

The average free hydrochloric acid estimation in 436 cases of inoperable gastric cancer was 7.46. The average total acidity was 28.3. The average combined acidity was

21.0. Lactic acid was present in 62 per cent. of this group. The average free Hcl in 65 cases of ulcerated primary cancer was 2.0. The average total acidity was 34.0. The average combined acidity was 31. Lactic acid was demonstrated in 63 per cent. of this class. The average free hydrochloric acid estimation in 119 cases of gastric ulcers that had undergone malignant change was 33.4. It ranged from 4 to as high as 120. The average total acidity was 51.0. The average combined acid was 16.0. Lactic acid was present in but 23 per cent., or in approximately one case out of five. In the primary cancer group, lactic or other organic acid was demonstrated in 54 per cent. of the gastric extracts. In the group of cancers seemingly following a chronic gastric ulcer, lactic acid was present in 42 per cent. More than 65 per cent. of cases showing lactic acid revealed free Hcl absent, and in 75 per cent. the demonstration of lactic acid was associated with interference with the stomach's emptying power. Tests for occult or altered blood by the benzidin or the guaiac methods, were positive in 72 per cent. of the total test-meals of the series. The glycyltryptophan test was positive in 40 per cent. In 141 cases of cancer, or 65.1 per cent., the Wolff test was positive; in 29 cases (13.4 per cent.), the test was suspicious. Gastric extracts from 15 cases of ulcus carcinomatosum were tested. In 11 instances (73.3 per cent.), the test was positive; 3, or 20 per cent., were suspiciously positive.

62. **Reactions Between Bacteria and Animal Tissues.**—Smyth gives an outline of the results of observations on over 1,100 tissue cultures. The reaction of bacteria to tissue cultures would seem to be more or less parallel to the pathogenicity of the organism for the animal supplying the tissue. This method promises a reliable means of differentiation between some pathogenic and non-pathogenic organisms of the same species. It will probably shed more light on the protective action of tissue cells and cell products against bacterial action, as is seen with splenic cultures. It will probably explain more clearly the action of pathogenic bacteria and the definite relation they bear to the tissues involved and to the blood plasma, as is seen from the peculiar behavior of *Bacterium diphtheriticum* in tissue cultures.

65. **Action of Substances Inhibiting Tumor Growth.**—The authors' later investigations confirm their previous results. They claim that it is possible to increase markedly the effect of substances inhibiting tumor growth by using certain combinations of these substances which, when given alone, have some effect on tumor growth. Immunity acquired against the effect of these substances depends partly on an active immunization of the tumor cells themselves against the action of these substances, and this immunity is transmitted to the following generations of tumor cells. The immunity against the substances inhibiting tumor growth is, so far as Fleisher and Loeb have investigated the problem, specific. Their later experiments provide a more secure basis for the additional and more general conclusions mentioned tentatively in a previous paper.

66. **Transplantation of Thyroid Tissue in Guinea-Pig.**—Summarized briefly the principal result of Hesselberg's experiment was, that for a short period of time after operation no difference is seen in the behavior of the thyroid after autotransplantation and homeotransplantation. Very soon, however, a destruction of follicles begins to take place in the homeografts. This destruction is not caused by a direct primary disintegration or solution of follicles, but depends on the destructive activity of (1) the lymphocytes, and (2) of the connective tissue of the host tissue. The former invade the follicles and destroy them directly; the latter grows into the homeografts in larger quantity than into the autografts. In the former it soon becomes fibrous and hyaline; in the latter it remains cellular. The fibrous connective tissue surrounds and compresses and thus destroys the follicles. In some homeografts, destruction by means of lymphocytes, in others by connective tissue, preponderates. The rapidity with which the destruction takes place in different homeotransplants also varies. A much better blood vessel supply develops in the autografts than in the homeograft.

78 Specific Precipitin in Blood of Persons Injected with Antidiphtheric Horse Serum. C. W. Wells, Chicago.
79 *Fecal Flora of Typhoid and Its Reaction to Various Diets. J. C. Torrey, New York.

70. **Effect of Quinin on Rabies.**—Of four dogs treated with quinin, one showed a prolonged period of incubation and another showed a remission in the course of the disease, in either case, however, not beyond variations in the natural course of the disease. The fact that these variations occurred in the two of four dogs receiving the largest amounts of quinin Krumwiede and Mann regard as being probably only a coincidence. No influence was observed on the period of incubation in rabbits.

71. **Virulence of Sensitized and Non-Sensitized Typhoid Bacilli.**—According to Cecil his experimental work showed that sensitized, living typhoid bacilli, when injected intravenously in rabbits and guinea-pigs, are less virulent than non-sensitized, living typhoid bacilli. Sensitized typhoid bacilli, killed by heat, are in a similar way less virulent than non-sensitized, killed typhoid bacilli. The most probable explanation in Cecil's opinion for this difference is that sensitized typhoid bacilli undergo phagocytosis and bacteriolysis more rapidly than the non-sensitized bacilli.

74. **Sodium Sulphocyanate in Tuberculosis.**—Sodium sulphocyanate was found by Corper to be lethal to rabbits when given intravenously in amounts of 0.4 to 0.6 gm. per kilo. Delayed death may occur even from smaller amounts. When injected intravenously (about 0.4 gm. per kilo), it is found in the tuberculous tissues in concentration about equal to that in the blood (0.06 to 0.08 per cent.). The concentration in the lungs, heart, kidneys, and testes is not far from that in the blood, the concentration in the liver is less, while it is practically absent from the muscles. It disappears

from the tissues (normal and tuberculous) as speedily as it does from the blood (being absent about five days after injection). No evidence of a chemical affinity of the sodium sulphocyanate for any of the normal or tuberculous tissues was obtained. Tubercle bacilli, exposed to concentrations of sodium sulphocyanate up to 1 per cent. for forty-eight hours at 37 C. and up to 0.1 per cent. for seven days at 37 C., were not killed. No evidence even of attenuation was observed.

75. **Tellurite Test for Viability of Tubercle Bacilli.**—As a result of an attempt to use the Gosio vital reaction (sodium tellurite) as an index of life of virulent human tubercle bacilli in bactericidal experiments in connection with chemotherapeutic work; Corper found that it was not an available general reagent for this purpose, at least by the methods tested. Nevertheless, by its use a simple, rapid test was developed for determining the viability of cultures of tubercle bacilli, of value especially in eliminating such loss of time as may be occasioned by working with dead instead of viable cultures. A small lump of the culture to be tested is placed in the cup of a sterile, hollow glass slide and one or two small drops of sterile 0.2 per cent. sodium tellurite in distilled water are added; it is covered with a sterile glass cover slip bordered with sterile vaselin, and placed in the incubator at 37 C. Life of the organism is indicated by the blackening of the lump of culture, which occurs in from thirty minutes to two hours. Sodium tellurite is lethal to rabbits when it is given intravenously in amounts of about 0.8 mg. per kilo. It does not kill the tubercle bacillus even when in 0.01 per cent. concentration in salt solution or glycerol broth for forty-eight hours at 37 C., nor does it inhibit the growth in 0.001 per cent. concentration on glycerol agar.

77. **Effect of Quinin in Rabies.**—Quinin failed to be regularly effective as a cure or preventive of rabies in the animals used by Moon in his experiments. Quinin, given in the latter stages of hydrophobia in two human cases, produced no significant results. Quinin appeared to retard somewhat the development of street rabies if given in large doses during the incubation period. The results indicated that the organism, which causes rabies, is influenced in some degree by quinin. This Moon regards as being significant as showing that the organism is susceptible to therapeutic measures, and gives reason to hope that some drug may be found which will be of value in the treatment of hydrophobia.

79. **Diet and Fecal Flora in Typhoid.**—In a series of typhoid cases, studied by Torrey, the intestinal flora as revealed by examinations of the stools soon after the admission of the patients to the hospital was not uniform or specific in type, but exhibited variations that might be observed in a series of supposedly normal individuals. Apparently, the character of the intestinal flora is not a factor concerned in the determination of susceptibility to typhoidal infection. On a diet consisting of a daily average of from 50 to 100 gm. of protein, from 75 to 100 gm. of fat, and from 250 to 300 gm. of carbohydrate, including lactose, the intestinal flora tended to become simplified in regard to the variety of bacterial types observed in direct Gram-stained smears from the feces and in cultures and to become converted into a fermentative type in which the dominant organism was *Bacillus acidophilus*. The degree of this transformation was dependent largely on the type of flora which was present at the onset of the disease. When the flora showed a definite putrefactive tendency, the change did not extend farther than the elimination of the obligate putrefactive organisms and a moderate development of the aciduric types; while, with a more favorable initial flora, the change was of so radical a type that the stools finally resembled those of the first few years of normal infancy in the dominance of *B. acidophilus* and even in the presence of *B. bifidus*. Such a flora is not an obligate fermentative one and under the conditions of feeding is not capable of forming indol. Observations on a few patients given a purely milk diet indicated that this food alone does not bring about this transformation of the intestinal flora to such a degree as that which may follow a more liberal carbohydrate feeding. Patients exhibiting an initial fermentative flora of the aciduric type adapted themselves more readily to the high calory diet of Coleman, as shown especially by a comparative freedom of distention, than did patients with floras of putrefactive tendencies; in such patients, the diseases showed a marked tendency to run a mild course. The typhoid bacillus was isolated from the stools of these patients on a high calory diet less frequently than has been reported for other series of cases in which the feeding was less liberal.

80 *Neuroplasty of Median and Ulnar Nerves. R. E. Weible, Fargo, N. Dak.
81 Work of European War Surgeon. O. A. Oredson, Duluth.

80. **Neuroplasty of Median and Ulnar Nerves.**—The inner side of the whole upper right arm of Weible's patient was ground out by the rapidly moving knives of a mowing-machine. The portion destroyed included muscle, artery and vein, the internal cutaneous nerve, and the median and ulnar nerves. The musculospiral nerve escaped because of its depth. Four or five days later Weible saw him. Any attempt to use the arm resulted in extension of the hand on the wrist with the fingers in a flaccid, partly closed position—the "main en griffe." Sensation was gone over most of the forearm and hand. While there was some difficulty in finding the nerves, due to the dense cicatricial tissues, the neuromatous ends were eventually discovered, and the nerves freed. Nearly 13 cm. of the median and ulnar nerves were missing.

To perform the neuroplasty it was found necessary to split both the proximal and the distal portions of each nerve to secure enough flap material to bridge the gaps. This splitting extended near to, but not into, the neuromas; and at this point careful examination was made to see that the nerve fibers showed distinctly clear to the end of the incision in the nerve. The neuromas were not removed; but between each two a tension suture was placed. With a few sutures the median nerve was buried in the biceps muscle, and the ulnar in the triceps. The wound was closed without drainage.

In three weeks the patient was complaining of tingling and burning sensations in the forearm and hand. The first sensation to return came in the little finger, in the outer half of the ring finger, and the ulnar side of the hand; and motion followed in the same order. Motion came next to the middle finger, and finally to the index finger and thumb. Four years after operation the little, ring and middle fingers functionate in a perfect manner. The short flexors of the index finger and thumb are normal, while the long flexors are just beginning to act. The muscles of the arm have developed wonderfully well, and the hypothenar eminence and the ulnar side of the hand are as round as ever they were. The ulnar nerve is completely restored; the median, nearly so. The only branches of the latter that are not fully developed are the anterior interosseous nerve and the muscular branch in the hand. The tactile sense is still incomplete. He uses his hand well, and for the past year has handled a team of horses from his seat on a livery carriage.

Journal of Nervous and Mental Disease, Lancaster, Pa.

84 Case of Probable Encephalitis Due to Inhalation of Fumes of Gasoline. C. S. Potts, Philadelphia.
85 *Diagnostic Value of Hallucinations: Based on Study of Five Hundred Cases of Mental Disease. A. W. Stearns, Boston.

82. **Spinal Decompression in Meningomyelitis.**—It is held by Taylor and Stephenson that selected cases of meningomyelitis are susceptible to surgical treatment, in which the findings indicate the segmental level. This treatment should consist in laminectomy, free opening of the dura, and, probably, incision into the posterior columns of the cord, espe-

cially in those cases showing marked infiltration and swelling of the cord. This operation, properly performed, adds very little to the jeopardy of the patient, but, on the contrary, seems to greatly diminish the period of convalescence and to lead to a more nearly normal return of function in the cord than is usual in these cases when treated expectantly. Many surgeons have demonstrated that laminectomy is not a very dangerous operation. Decompression probably acts favorably by causing freer circulation, with the more rapid absorption of the inflammatory exudate. Incision of the cord probably facilitates drainage. The small risk inherent in laminectomy, and the great advantage likely to accrue to the patient, argue much in favor of the surgical treatment of these cases. The same facts also argue for the earlier employment of exploratory laminectomy in most spinal cases in which the diagnosis is not perfectly clear, but cases in which the symptoms point to some cord level as the seat of trouble.

85. **Diagnostic Value of Hallucinations.**—Of the 31 cases of alcoholic hallucinosis studied by Stearns, 100 per cent. were hallucinated, 97 with auditory, 4 with visual and 13 with other types. Examination of the delirium tremens group showed that 100 per cent. of the 14 cases were hallucinated, 78 auditory, 85 visual and 14 other types. Of 105 cases of dementia praecox 70 per cent. were hallucinated, 68 auditory, 21 visual and 10 other types. Of the 31 cases not showing hallucinations, 11, though the patients denied such presence, showed some evidence of their existence, 3 were catatonic and did not speak, 6 could not be examined because of violence or language difficulty, and in only 11 cases, or 10 per cent., could it be fairly said that they were absent. Of two brain-tumor cases one patient thought he heard the voice of a friend calling and this may have been an illusion. Of five toxic cases, two patients had indefinite hallucinations which were not unusual. Of three epileptics who had hallucinations, one had the visual, one the tactile, and one the gustatory type. Twenty-seven per cent. of the unclassified cases were hallucinated. Twenty-five per cent. of the general paralytics were hallucinated, 24 of the auditory and 11 of the visual type. No two of these were alike, and in but two cases were hallucinations a prominent symptom. In only one out of four cases of cerebral syphilis was there a history of hallucinations and this one was rather definite. In Korsakow's disease, 27 per cent. admitted hallucinations, these usually occurring in a delirious onset. In the manic-depressive group, but 18 per cent., were hallucinated. Thirteen per cent. of these were auditory and 9 visual and in 54 cases but 10 patients had hallucinations. In none of these were they a prominent symptom and in many there is reason to doubt their existence. Seven of these 10 were manic and 3 depressed.

The following conclusions are drawn by Stearns from this work: 1. The presence of hallucinations is indispensable for the diagnosis of alcoholic hallucinosis or delirium tremens, but the type of hallucinations is not a proper criterion for differentiation between these diseases. 2. The frequency of hallucinations in dementia praecox and their rarity in manic-depressive insanity has a bearing on differential diagnosis (provided that psychopathic hospital criteria are sound for these two diseases). 3. There are some grounds for doubting the existence of true hallucinations in manic-depressive insanity. 4. Hallucinations seem to be rare in sane persons, even though they be psychopaths.

99. **Intoxication Impulse.**—The last four years have forced on Lambert the belief that the majority of periodic drinkers who are endeavoring hopelessly to cease their periodic sprees are really cases of chronic tobacco poisoning. This is seen more frequently among the incessant cigarette smokers than among those who usually smoke a pipe or cigars. It is seen most commonly among those who always inhale their tobacco smoke. Drugs are absorbed by the tracheal mucous membrane as quickly as by subcutaneous injections. The effect of the pyridin and collidin, and other substances contained in tobacco smoke, is quickly felt by those who inhale. The ease with which cigarettes can be smoked, the universality of the habit, and the accepted permission that a cigarette can be smoked often in cases in which a pipe or a cigar cannot, add to the frequency of the cigarette indulgence. Tobacco at first is used to soothe the nerves, and is taken for its soothing effect. In the early stages it slightly quickens the circulation and thus increases cerebral action. It, therefore, helps in mental rapidity in the early stages of moderate indulgence. Soon it is the accepted panacea for any worry or disturbance of the equilibrium of daily life. Then it is soon necessary to have a certain number of cigarettes that a certain amount of the narcotic may be absorbed to smooth out the daily existence. In this stage of tobacco poisoning the lotos eating contentment and mental inertia are evident and further over-indulgence brings on a nervousness which, in the beginning, a very little more indulgence in tobacco will allay. Soon, however, the more tobacco that is smoked and the more that is inhaled, the greater is the nervousness. It has then ceased to produce its narcotic effect and is producing its chronic poisoning. The individual therefore turns to something that he knows will have a narcotic effect and quiet his over-wrought nerves. This he knows alcohol will do, and in these individuals the first drink of alcohol leaves them not sober and starts in them its narcotic craving which drives them on to the full expression of their spree. As they sober up they cease for a few days both smoking and drinking, and as soon as they are over the spree they begin to smoke again and the vicious cycle is sooner or later completed. Lambert is firmly convinced that this double narcotic poisoning explains the majority of the periodic drinkers of to-day. If these patients are made to cease their smoking their drinking ceases automatically. It is the expression of an uncontrollable poisoning.

101. **New Remedial Agent and Its Effect in Pulmonary Tuberculosis.**—Waters claims that when the vapor of pinene is exposed to a current of ozonized air, prepared by the action on dry air of a high tension electric discharge, an addition occurs between the pinene and oxygen, resulting in the production of a dense white vapor. To this substance he has given the name oxypinene. It is chemically a pinene monozonide, occurs also as a diozonide and other multiples of the oxygen atom, and readily dissociates into its active principles, peroxid of hydrogen and pinonic acid, aldehyd

and ketone. Waters says that it possesses the valuable therapeutic properties of pinene without its irritating effects on the kidneys and urinary tract. Applied to the skin and mucous membranes it acts as a mild stimulant, markedly differing in this respect from the powerfully irritating oil of turpentine. The vapor is respirable for hours at a time, and its use may be continued indefinitely day after day without producing symptoms of renal irritation. It is antiseptic and bactericidal when applied to cutaneous and mucous surfaces. Bacteriologic experiments have been repeated many times, in the same manner, with uniform results, and from them it seems that oxypinene is a germicidal gas, of high efficiency, which is at once respirable and easily produced, continuously, in large quantities.

125 and 127. Abstracted in The Journal, Dec. 5, 1914, p. 2068.

128. Also published in *Medical Record*, Jan. 2, 1915, and abstracted in The Journal, February 6, p. 541, abstract No. 72.

129. **New Complement-Binding Reaction in Syphilis.**—The serum of a patient who was unquestionably clinically syphilitic, and who later responded perfectly therapeutically, was heated by Harris to 71 to 72 C. (159.8 to 161.6 F.) for twenty minutes; 5 drops of this serum, as well as that of others similarly treated, were used as antigens. With this change the technic of Noguchi was followed. It was found that the serum of syphilitics with antibody eliminated by heat acted as antigen and gave complement binding with the serum of other syphilitics. Serums which had given antibody reactions were in turn found to act as a finder for antigen in other serums which had been heated to 71 to 72 C.

1. **Treatment of Malignant Disease by Radium Irradiation.**—The effect of exposing malignant cells to radium irradiation, according to Morson, is as follows: 1. Rapid degeneration of the malignant cells in the immediate vicinity of the tube of radium. 2. Apparent vacuolation and enlargement of nuclei of those cells beyond the degeneration zone. 3. Loss of the reproductive function of the cancer cell. About the third day after treatment the connective-tissue cells commence to proliferate. This action of radium on the connective-tissue cells shows a similarity to the attempt of nature to arrest the growth of cancer through new formation of fibrous tissue. If an excessive quantity of radium or too prolonged an exposure be given, not only necrosis of the whole tumor results, but the normal tissues slough also. Owing to the sensitiveness to irradiation of the endothelium which lines blood vessels, thrombosis is liable to occur. The vascular supply of the malignant tumor may thus be interfered with.

The microscopic changes which have been described can only be detected when the malignant cells are exposed to the rays in the body. The author has made experiments with a view to finding out whether by irradiating tumors outside the body it is possible to detect similar changes. Portions of growth suspended in the patient's blood immediately on removal have been submitted to irradiation for twenty-four hours at body temperature. No differences in microscopic appearance were observed between these and the controls, which were kept under similar condition but non-irradiated. When a malignant tumor has apparently disappeared after radium treatment, a thickening of the tissues, due to proliferation of the connective-tissue cells, is found to have taken place. If the treatment has been successfully carried out, no active inflammatory changes are detectable. In the normal tissue there is a marked increase in sensitiveness to irradiation when radium is applied a second time. Pigmentation of the skin and telangiectases are common sequelae of radium irradiation. No evidence has yet been brought forward to show that diminution in size takes place in visceral, skin or bone metastases after removal of the primary growth by radium treatment. In a few cases, however, a decrease in the size of the gland metastases has been observed.

3. **Ossification in Sarcoma of Bone.**—Three cases of endosteal sarcoma in which ossific changes took place are cited by Knaggs and Gruner. The new bone formation was independent of the periosteum. The active element in the process appeared to be the sarcoma cell. It is around this cell that the calcareous particles were deposited, sometimes in well-marked granules, sometimes as a haze in which the particles were too small to be recognized, but eventually thickening into non-laminated trabeculae of irregular shape. The process did not seem to be preceded by a tendency to necrobiosis—the explanation of ordinary calcareous degeneration—for in cases in which ossification was proceeding rapidly there was usually a very marked increase in the connective-tissue development, and the nuclei showed well, and the vascularity was marked. Often also there were signs of a tendency to definite arrangement which the authors believe justifies the use of the term ossification rather than that of calcification, and which is opposed to the idea of death. On the other hand, the cells showed a tendency to shrink, or, in the case of the giant cells, to lose their numerous nuclei after inclusion or as the calcification process began. Just as in a chondrosarcoma, when ossification begins, the lime salts are deposited in the matrix in the immediate vicinity of a cell, so in these cases the calcareous particles are laid down in the intercellular substance. Not only was the bone formation independent of the periosteum; in all three cases it occurred chiefly within the limits of endosteal bone formation.

4. **Treatment of Urethral Stricture by Excision.**—In all cases of stricture that are not easily managed by dilatation, excision of the stricture is advised by Russell. In all cases of stricture that are easily managed by dilatation, no further operation is advised; nevertheless, even for patients in this category who may desire to be rid of even a moderate stricture, the operation, in his opinion, offers a safe and efficient remedy. This operation should entirely supersede both internal and external urethrotomy as now performed.

6. **Tibiocalcaneal Resection with Amputation of Remainder of Foot.**—A method of amputation at the ankle-joint which leaves the heel intact produced excellent results in the seven cases operated on by Watson, and, in his opinion, has provided more serviceable stumps than could have been obtained by Syme's or Pirogoff's amputations. The main principles of the operation are to leave the original walking-surface of the heel intact, and to preserve the malleoli; to amputate the foot in front of the os calcis, together with the astragalus; to remove the cartilaginous surfaces of the lower ends of the tibia and fibula and of the upper surface of the os calcis; and then to wedge the os calcis between the malleoli, and pin it there with an excision pin driven through the heel (to be removed in about a fortnight).

The following advantages are claimed for the method: 1. The patient walks on the original heel-pad, which has been accustomed to carry weight and to bear pressure. 2. A club-shaped stump is secured by not removing the malleoli, which gives a firm hold to the "uppers" of an ordinary boot. 3. The shortening of the limb is reduced to a minimum (about an inch on the average). 4. No expensive artificial apparatus is necessary. An ordinary boot can be worn (a great advantage for hospital patients) if the sole is stiffened with a sheet of metal and a block provided for the toes. 5. Owing to the original heel-pad being left intact, weight can be borne on the stump at an early date without risk of pain or undue pressure. The method may be employed in lieu of Chopart's amputation (when this operation is possible) without the risk of backward tilting of the os calcis from contraction of the tendo Achillis. Less skin is required for the dorsal flap than in Chopart's amputation, and the stump is no less serviceable for walking.

10. **Ununited Fractures Treated by Long-Axial Drilling of Fractured Bone-Ends.**—The operation emphasized by Wildey consists in thoroughly exposing and cleaning the ends of the fragments at the seat of the fracture, refreshing them by removing the thinnest possible transverse section of bone that will ensure a complete removal of all dense fibrous tissue, and drilling, in the long axis of the shaft, several channels in the indurated bone-ends; the effect of this maneuver is the production of an artificial porosity of the osseous tissue. The drill is made to penetrate to healthy bone; at the same time the medullary cavity, which may be found occluded, is made patent by longitudinal perforations. Apposition and immobility of the fragments are secured by plates or other mechanical means. This method, which has been employed in many cases of long-standing non-union, has not failed to produce an abundant callus. Gratifying results have been obtained in cases in which a previous and unsuccessful operation had so shortened the limb that any further removal of the indurated bone must have left functional disability.

12. **Treatment of Acute Emphysematous Gangrene.**—Attention is directed by Lawson and Whitehouse to a new method of treatment of emphysematous gangrene. Half an hour before operation the patient receives a hypodermic injection of 1/100 gr. of atropin sulphate and ¼ gr. of morphin tartrate. General anesthesia as a rule is employed; but if the patient is profoundly septic, and the wound involves the lower extremity, spinal anesthesia is preferred. A point is then selected three or four fingers' breadth above the line of advancing gangrene, as shown by the dusky copper-colored tint of the integument. An incision about ¼ inch in length is made through the skin and subcutaneous tissues as far as the fascial sheath of the muscles. A pair of sinus forceps is then introduced into the wound, and the whole of the subcutaneous tissue opened up as widely as possible. The nozzle of an ordinary Higginson's syringe is introduced into the incision, and neutral hydrogen peroxid (10 volts) at body temperature is pumped into the subcutaneous spaces under pressure. The dissemination of oxygen is aided by kneading and massage. It is essential that the belt of oxygen be complete above the line of advancing gangrene, and therefore it is usually necessary to repeat the procedure at various points. This done, the gangrenous area itself is treated in a similar manner by puncture and infiltration. Finally, the wound is thoroughly explored and cleansed. All foreign material, dead and contused tissue is removed, and the cavity irrigated with normal saline (in order to wash away débris and clot), and then freely with hydrogen peroxid. Drainage by rubber tube and gauze is established, and the whole limb dressed with dry gauze and wool. Although much drainage may be anticipated, the authors consider it a mistake to employ huge quantities of wool and gauze in these cases. The aim should be to allow free access of air, coupled with efficient protection to the wounded tissues.

16 *Study of Basis of Abderhalden's Serum Reaction. W. E. Bullock.
17 Electrotherapy at Base Hospital. W. J. Turrell.
18 Fear and Disease. E. T. Jensen.

14. **Telephone Attachment in Surgery.**—Davidson advocates the adoption of a telephone, preferably with double receivers, connected together by means of a steel or elastic band, so that each ear has its separate receiver. This not only increases the intensity of the sound, but also serves to cut off extraneous sounds which might interfere with the audibleness of the telephone. Should the surgeon wish to have one ear uncovered so as to be able to attend to the remarks of anyone near him, it is quite a simple matter to move aside one of the

receivers. This double arrangement, however, is not essential, and a single telephone gives quite good results if the surgeon's hearing is acute. The carbon plate is placed on the patient's moistened skin, and plaster or bandage may be used for holding it in position tightly against the skin. The other end of the telephone should have attached to it a bare wire, of silver preferably, which has been disinfected by boiling or otherwise as the surgeon may direct. One end of this wire being attached to the telephone terminal, which, of course, cannot be disinfected readily, the other end need be handled only by the surgeon or his assistant with the usual antiseptic precautions, and the wire can either be wound round any instrument it is desired to use, or a spring clip may be employed by means of which the wire can be conveniently brought into connection with the knife, probe, needle or forceps, as the case may be.

Under these conditions, if the instrument is introduced into the body it will on first contact with any metal give rise to an unmistakable click carried through the telephone, and then, if it be gently moved or slightly disturbed so as to make a rubbing contact with the foreign body, an equally unmistakable loud rattle will be elicited. By such means the metal can be dissected out (if the knife is used) or otherwise freed from the encircling tissues, because a constant control can be exercised over the foreign body by reason of the microphonic rattle it produces when the instrument comes into contact with it. In cases in which a foreign body has been carefully localized by means of Roentgen rays, a needle can be attached to the telephone in the manner stated, run down on to the foreign body, and, when the characteristic sound is heard, can be maintained in its position as a guide before any incision is made. The telephone attachment to forceps is particularly useful, because these can be used as a probe, and when the foreign body is between the jaws a characteristic sound is evoked.

16. **Abderhalden's Serum Reaction.**—The chief object of Bullock's work was to test the reliability of the reaction as applied to the diagnosis of cancer. It was found impossible to cause the production in rabbits of a ferment which digests coagulated egg albumin by the injection subcutaneously, intraperitoneally, or intravenously of raw egg albumin. A minute quantity of amino-acids is present in 10 c.c. of blood serum of rabbits and dogs, and it was found (in rabbits) that after a bleeding these substances are increased in amount. An autolytic ferment is found in the blood serum of rabbits, of dogs and in human serum. The serum of the pregnant rabbit is unable to break down rabbit placenta, and the serum of the pregnant bitch is unable to break down dog placenta. Human blood serum from the pregnant female and from healthy male, incubated with human placenta, produced by chemical or physical action amino-acids.

Rat blood serum ("normal" and "tumor") breaks down rat tumor. Guinea-pig serum ("normal" and "tumor") breaks down guinea-pig tumor and mouse tumor. The blood serum of the guinea pig was not rendered more active in this property by a previous inoculation of the animal with mouse tumor. Bullock asserts, therefore, that the method devised by Abderhalden is inadequate to distinguish normal from pregnant or cancerous serum. The fundamental experiments adduced by Abderhalden do not, on repetition, give the results stated by him, and a proteolytic ferment normally present in the serum of mammals acting on tissue substrates of varying lability, prepared in accordance with his directions, in all probability accounts for his results and their confirmation by others.

23 *Paroxysmal Tachycardia. E. Donzelot.

December, No. 12, pp. 657-688

24 *Radiotherapy in Severe Anemia. H. Vaquez and C. Aubertin.

19. **Pernicious Anemia in Roentgenologist.**—Aubertin has previously pointed out that in the blood of persons having much to do with radiant energy the leukocytes are frequently much modified, the numbers extremely low, with hypopolynucleosis and eosinophilia. The reds never seemed to suffer in the cases examined, but an exception to this rule has been afforded by the tragic fate of Dr. Tiraboschi who has recently succumbed to progressive pernicious anemia. The blood-producing organs were found the seat of important changes, especially the spleen which was in pronounced atrophy. He had been in charge of the Roentgen department of the Bergamo hospital in Italy for fourteen years, and at one time had a Roentgen dermatitis which soon healed without ulcerating. His two sons are healthy. The atrophy of the spleen and the content in iron-containing pigment were beyond anything Aubertin has ever encountered. These findings resembled those in animals after repeated intensive Roentgen exposures, and suggest that the Roentgen rays are liable to induce a special pernicious anemia in certain cases.

22. **Pulsation in the Femoral Vein.**—In the three cases related there were disturbances in the right heart, and the pulsation in the femoral vein was of auricular origin. In two of the cases there was also a presystolic pulsation in the liver. This abnormal femoral venous pulse could be detected by careful palpation, and this revealed the presence of the heart disease and aided in localizing it when clinical and roentgenoscopic examination was negative.

23. **Paroxysmal Tachycardia.**—Donzelot classes paroxysmal tachycardia as the regular, total type; the partial type, sometimes called auricular flutter; and the irregular type, that is, with attacks of complete arhythmia. In the first type the tachycardia comes on suddenly, in the midst of apparent health, with a sensation of shock in the chest, and the delirious heart action ceases as abruptly as it began. In the intervals between the attacks the individual seems to be in the best of health. When these attacks are few and far between the heart does not seem to suffer, but if they grow longer and more frequent, the myocardium gets worn out and serious mischief results. The different types may blend into each other or be superposed, and it is not unusual to see the progression through the three types to a fatal conclusion. No mention is made of treatment. (See abstract 43 in these columns Feb. 6, 1915, p. 546.)

24. **Roentgen Treatment of Severe Anemia.**—In large doses, the Roentgen rays have a destructive action on the bone marrow, but in small doses they merely stimulate it to better functioning. This at least is what Vaquez and Aubertin conclude from the favorable results of Roentgen exposures in a case of severe anemia probably the result of long, mild carbon monoxid poisoning. The reds numbered 750,000, the whites 4,800, hemoglobin 15 per cent. and the man of 41 was too weak to be up and about. Marked improvement followed a course of very mild Roentgen exposures. In a girl of 14 with febrile anemia, seven Roentgen exposures in the course of a month produced a marked improvement, the patient keeping comparatively well for a year; then the anemia returned and proved fatal in spite of a renewed radiotherapy and other measures. Some other cases are cited, all demonstrating that benefit may be expected when the blood marrow is still capable of responding to the stimulation. When it has degenerated beyond this, nothing can be hoped from the treatment. The outlook can be determined by examining the blood repeatedly during the course of exposures. If the numbers of nucleated cells increase, improvement may be counted on, but if the number of nucleated cells does not vary, the prognosis is grave. The radiotherapy seems to act in the same way as arsenic. In cases of mild anemia other measures seems to deserve the preference, although Grego has reported excellent results in two cases of neurasthenia with chloro-anemia given 2.5 H units at three-day intervals for three weeks. Similar benefit was

realized in a case of anemia from excessive loss of blood. With these small doses the reds and hemoglobin percentage increased without any drop in the number of whites. Vaquez and Aubertin applied the rays with the same technic as for myeloid leukemia, especially to the knees, shoulders and elbows, and occasionally, the sternum. The rays are filtered through 2 or 4 mm. of aluminum. In one case the first dose was too large (18 H units scattered over the different epiphyses of the long bones), and the immediate result was a temporary aggravation of the anemia.

Archives de Médecine des Enfants, Paris

September, XVII, No. 9, pp. 641-720

25 *Diphtheria Bacilli Carriers. (Quelques documents relatifs à l'étude des porteurs de germes diphthériques.) J. Renault and P. P. Lévy.
26 *Urea Content of Cerebrospinal Fluid and the Ash in the Stools with "Atrophy of Infants." (Azotémie et cendres des matières fécales chez les athrepsiques.) Nobécourt and C. Bidot.
27 *Treatment of Inguinal Hernia in Children. A. Nota.
28 Exophthalmic Goiter in Girl of Seven. G. Railliet.
29 Nitrogenous Bodies in Blood of Children. (L'azotémie chez les enfants. J. Comby.

25. **Diphtheria Bacilli Carriers.**—Renault and Lévy made weekly smears from the throats during two months in a school connected with a hospital and in two hospital wards. A total of 784 smears were made, including some from the relatives of 44 of the children who had recently had diphtheria. They give charts showing the percentage of carriers. The constant arrival of new inmates for the school and wards made the findings very variable, but the number of carriers invariably showed a marked increase when a child entered who had recently passed through diphtheria or one developed it in the school or ward. The closer neighbors of the diphtheria case nearly always had diphtheria bacilli in their throats. The facts observed led to the adoption of the following rules, and long experience, they say, testifies to their being rational and safe: 1. In the family, when a case of diphtheria develops, and medical surveillance and hygiene can be counted on, no preventive injection of antitoxin is made, except to infants in arms. When it is doubtful if surveillance and hygiene can be enforced, all the members of the family are given a prophylactic injection. 2. In schools and asylums, medical supervision and strict hygiene are not always attainable, and consequently the children should be closely watched if a case of diphtheria develops. If a second case appears, then every one must be given the preventive injection. 3. In the hospital, as the supervision here is perfect, there is no need for preventive antitoxin unless an epidemic threatens. This is rendered probable when two cases of diphtheria develop close together. Very young children and those with measles should always be given a preventive injection even if only one case develops in their ward.

26. **Metabolic Findings in Atrophy of Infants.**—The metabolic findings in five extremely debilitated infants are tabulated, showing that such infants are uremic, and that the azotemia increases as the cachexia becomes more pronounced, and subsides as health returns. The azotemia was estimated by the urea content of the cerebrospinal fluid.

27. **Inguinal Hernia.**—Nota's method of treating inguinal hernia in children is by introducing a deep crescent cut out of a sheet of paraffin. It was described in these columns, Sept. 12, 1914, p. 980.

30 *Cesarean Section after Rupture of Fetal Membranes. (Cesariennes tardives.) E. Zarate.
31 Antigonococcus Vaccine and Serotherapy in Gynecology and Obstetrics. E. Gaujoux.

30. **Tardy Cesarean Section.**—Zarate describes from his experience at Buenos Aires four cases in which the classic cesarean section was applied as an emergency measure four, twelve and sixty-two hours after the fetal membranes had ruptured. The outcome was excellent for both mother and child in each case. The uterus was drawn out through a long median abdominal incision, the lips of which were held together with forceps behind the uterus, the abdomen protected with compresses. A sheet was then drawn over the uterus and the assistant kept this smooth and fitted down to the curve of the uterus even when the organ retracted after incision and evacuation. The interior of the uterus was thus protected, as also the tissues of the uterus wall against contact with the amniotic fluid. The membranes and placenta were removed with dry sponges. Then the interior of the uterus and the lips of the incision were swabbed out with a mixture of equal parts alcohol and tincture of iodin if the cervix was dilated. If not, he tamponed the cavity with medicated gauze, pushing a strip down toward the vagina. Then the protecting sheet was discarded and the uterus sutured. A little morphin was given four hours later to keep the viscera tranquil.

35 Congenital Atresia of Esophagus with Fistula into Trachea. G. Schmidgall.

32. **The Declining Birth-Rate.**—Herzberg quotes Moltke's saying that the declining birth-rate in France is equivalent to the French losing a battle every day, but he adds that Germany nowadays is not far behind France in this respect. In 1876 the birth-rate in Germany was 42.6 while in 1911 it was only 29.5. The rate is even less than this in the Mecklenburg province, having declined from 46.14 in 1810 to 25.7 in 1912. Herzberg proposes an internal colonization as the remedy, providing ways and means so that young men from the cities or rural districts might be aided to set up a farm and a household for themselves instead of swelling the ranks of the periodically unemployed.

41. **Calcium Chlorid in Treatment of Hay-Fever.**—This communication states that the use of calcium chlorid in treatment of hay-fever is based on the physiologic action of the drug, and hence it is rational and effectual. Hay-fever patients cured by it in 1913 had no return of their malady in 1914 but seem to be permanently cured. Others had their hay-fever very much attenuated, almost to a complete cure, and in the following season it appeared only in the attenuated

form. The cell nucleus in glands, muscles, ganglion cells and leukocytes requires calcium for its proper functioning. The utilization of food is more complete when calcium is being taken; this is evidently due to an increased production of enzymes, and this production of enzymes is a function of the cell nucleus. Other consequences of the intake of calcium are increased phagocytosis, strengthening of the constitution, and enhanced resisting powers to various morbid influences. The calcium salts reduce, further, the overexcitability of the nerves which leads to sneezing, etc.

Emmerich and Loew have always impressed on hay-fever patients that vegetables and fruit are of much greater moment for the mineral supply than meat or starchy foods or bread. Vegetables and fruit also contain the salts of organic acids, especially potassium salts, which in the body become oxidized and aid in maintaining the alkalinity of the blood; this in turn aids in the retention of calcium. A number of new cases are related including the case of a man of 41 who for years had had severe hay-fever from the middle of May to July, sometimes sneezing forty times in succession. He began in March to take the chlorid and for the first time in fifteen years had a summer free from hay-fever. The formula calls for 100 gm. crystallized calcium chlorid in half a liter of distilled water. Three teaspoonfuls of this are taken during the day, always with the meals. This dosage is no more than one gets in a pint of milk, and it seems to be entirely harmless. Loew has taken this dose daily for six or seven years without harm. Jacobi and Wolff-Eisner experimented with calcium salts to learn their action on the kidneys, but their experiments with very large amounts and on diseased kidneys have no bearing on the therapeutic use of the above small doses of calcium chlorid. Jacobi emphasizes this in particular, saying that he has witnessed very brilliant results from the latter. Wolff-Eisner remarks that the calcium probably has an inhibiting action only on morbid kidneys, as he could find no influence of the kind in his two cases with sound kidneys.

48. **Vermin.**—Prowazek has been experimenting with various substances to keep lice away and states that the ethereal oils are effectual for this while they do not soil the clothes nor expose to danger of fire. Oil of anise and oil of fennel were the most effectual in his tests, and he recommends inunction of the mixture of 30 parts pure oil of anise and 70 parts 96 per cent. alcohol. He cites Leuwenhoeck that the body louse has about 5,000 offspring in the course of two months. The nits hatch out in three or four days and are sexually mature in about eighteen days. Nits on the clothes can be destroyed by sulphur or steam, or by placing in an air-tight vessel in which benzin has been sprinkled.

54 Wounds of the Jaws. (Schussverletzungen der Kiefer und ihre Behandlung durch den Zahnarzt.) F. Steinschneider.

53. **Failures in Operative Treatment of Exophthalmic Goiter.**—The first installment of this article was reviewed last week. Here von Haberer gives further details of the case there described. He emphasizes that it was a typical example of status thymicus but with no suggestion of status lymphaticus; this confirms the assumption of the independence of the conditions. The case is chiefly instructive on account of the evidence it presents of the important part played by the thymus in the Basedow syndrome. This was the only fatal case among the twenty-three in which he has resected the thymus for exophthalmic goiter, and it is the only one in which he left a large proportion of the gland unmolested as it proved to be so much larger than he had supposed. The action of the thymus is shown by this case and others resembling it to be a toxic action on the heart. The extremely high temperature seems to be a special feature of the postoperative thymus trouble. In future, if delirium cordis sets in after an operation for exophthalmic goiter, he intends to expose the thymus and resect still more of it. In conclusion he reports a case of unfavorable results from operative treatment of exophthalmic goiter after a course of ten Roentgen exposures had been given beforehand. The symptoms had not been benefited in the least while the operation later was rendered much more tedious and difficult by the modification of the tissues under the Roentgen rays. The thymus had evidently not been reached by the rays. To waste time on Roentgen treatment is therefore futile and dangerous.

57. **Mechanism of Secretion of Urine.**—Leschke states that sodium ferrocyanid injected into animals, even in enormous amounts, is eliminated exclusively through the convoluted tubules in the kidneys, in which its presence can be unfailingly revealed by treating the kidney tissues with a silver nitrate solution and then with a photographic developer, as he describes in detail. The elimination of urea is shown up in a similar way by transforming it into a brown mercury salt, and this too is found only in the convoluted tubules. The phosphates and sodium chlorid also obey the same law. Even when extremely large doses are taken, no more of either is found in the glomeruli than corresponds to the low physiologic concentration in the blood serum. This histochemical technic thus demonstrates unerringly that the normal elements of the urine, the chlorids, phosphates, uric acid, purins, etc., are eliminated exclusively through the convoluted tubules. The glomeruli secrete only water in the physiologic solution, and never more than the physiologic proportions of the elements of the urine.

59. **Pharmacologic Tests of Disturbances in the Vegetative Nervous System.**—Lehmann made 700 tests on about 200 persons, injecting pilocarpin or epinephrin to study their action on the vagus and sympathetic systems. His findings did not confirm the statements of Eppinger and Hess in regard to antagonism between these nervous systems. He found that over 95 per cent. of those exceptionally susceptible to the action of epinephrin were likewise exceptionally susceptible to the action of pilocarpin, and vice versa. The young seem to be more sensitive than older persons. On the whole, the results of his research were disappointing. In many persons who manifested an intense reaction to the drugs, not a trace of any disturbance in the vegetative nervous system could be detected. On the other hand, certain patients presenting distinct vagus stigmata and reacting intensely to pilocarpin and treated with atropin on these indications, yet failed to show the slightest benefit from it. This corroborates the assumption that the disturbance is not in the vagus alone

but that the whole vegetative nervous system is deranged. Benefit was derived from the atropin in only a small proportion of the cases, but it was so promptly evident that there can be no question that it must be credited to the atropin.

The reactions to the three tests, with pilocarpin, with atropin, and with epinephrin are tabulated in 100 cases. The findings confirm anew that the reaction to the pharmacologic tests by no means parallels the clinical symptoms. They show further that the conception of "vagotony" is in need of revision, although it has thrown instructive light on the group of internal secretion disturbances and neuroses of organs. Extreme caution is necessary in estimating the significance of the reactions to the pharmacologic tests. In conclusion, Lehmann warns of the severe by-effects he occasionally encountered in persons given even a single dose of *epinephrin.* In 40 per cent. the temperature rose slightly, and in some persons there was pulsation in the carotids or epigastrium, extreme pallor, headache, vomiting and distress. The test injection was, to stimulate the vagus, 0.01 gm. pilocarpin; to paralyze the vagus, 0.001 gm. atropin; to stimulate the sympathetic, 0.001 or 0.00075 gm. epinephrin. The latter test was supplemented by 100 gm. grape sugar given three hours before the epinephrin. An interval of two days was allowed between the tests.

62. **Relations between Status Lymphaticus and Derangement in Internal Secretion.**—Pribram studied this question on 2,500 patients who have passed through his hands at Prague in the last few months. The only truly characteristic findings are follicles at the base of the tongue and the behavior of the epiglottis. Lymphocytosis is common and, especially with hypoplasia in the genital organs, eosinophilia and basophilia were frequent. The follicles at the base of the tongue were much enlarged in 80 per cent. of the 150 persons who presented signs of status lymphaticus. The epiglottis, on the other hand, was infantile or omega-shaped. In 30 per cent. the glands in the neck were enlarged, and in 33 per cent. there was a striking tendency to genu valga and brachia valga. Alimentary glycosuria was evident in 6 per cent. and lordotic albuminuria in 33 per cent. These various findings were often isolated, so that a typical combination of a number was extremely rare.

68 Organization of the Thrombus. T. Todyo.

66. **Ossifying Myositis.**—Goto reports five cases of traumatic circumscribed ossifying myositis and a number of experiments to reproduce it on rabbits, discussing the nature of the trouble and the best treatment. There seem to be three types: that in which the ossification proceeds from the periosteum, that in which it proceeds from the muscle tissue, and, thirdly, a combination of both. Treatment must vary with the type; the true periosteal ossification is merely a traumatic exostosis and as such is long in developing and no muscle fibers are found in it. The term "ossifying myositis" should be restricted to cases of muscular origin, although neither this nor the term "intramuscular osteoma" are strictly applicable, as there is no actual inflammation or tumor. The literature on the subject is discussed and also the points of difference between it and progressive multiple ossifying myositis. With the exostosis type, the functioning of the muscles is comparatively not much impaired. The shadow cast by the exostosis has clearer outlines than the shadow of a sarcoma, and the bone is harder to the touch.

In treatment of myositis, repose, application of heated air, hot baths and similar measures to promote the local circulation are beneficial, but too early massage is liable to injure further the tissues already demoralized by the trauma. Even cautious massage should not be attempted, Goto says, until the local hardness of the tissues is subsiding. The hardening generally starts in less than a week after the trauma. In prophylaxis, it might be wise to evacuate an intramuscular hematoma. Operative measures are not called for otherwise unless for persisting disturbances or when repeated Roentgen examination shows no signs of retrogression.

76 *Vesalius and Experimental Physiology. (Vesalius als proefondervindelijk physioloog.) G. Van Rijnberk.

69. **Vesalius.**—(The celebration of the fourth centenary of the "Luther of anatomy" has been world-wide, our exchanges from every land bringing tributes and mentioning historical exhibitions here and there in his honor. The one exception is the land that gave him birth, Belgium. The Journal's editorial tribute was published January 2, p. 57, and January 16, p. 248. Of the only two perfect vellum copies of Vesalius' "Epitome" said to be extant, one was preserved in the University of Louvain. The physicians with the German forces at Brussels held a meeting in Vesalius' honor on his anniversary.)

72. **Illustrations in Works on Anatomy Before and During Vesalius' Day.**—Van Rijnberk reproduces a number of quaint illustrations from the works of De Ketham, 1491; Da Carpi, 1522; Valverde, 1556, and Stephanus, 1545, comparing their works with those of Vesalius.

73. **Portraits of Vesalius.**—The portrait of Vesalius from his own "Fabrica" is given, as also the large picture showing him at work on a cadaver in a crowd of enthusiastic spectators. There is also a reproduction of the oil portrait in the Amsterdam medical-pharmaceutic museum and of the one in the Royal College of London.

74. **Vesalius and da Vinci.**—Jackschath was one of the latest to claim that not Vesalius but da Vinci must be regarded as the Father of anatomy. In an address before the German *Naturforscher* Congress a few years ago he accused Vesalius of plagiarizing from da Vinci. Van den Broek's testimony apparently refutes this, and while hailing da Vinci as the greatest figure in the renaissance of art, he shows that Vesalius began the new birth of anatomy. (Vesalius amassed means while professor of surgery and anatomy at Padua so that he was able to publish the results of his research in the handsome style they deserved, and thus spread his results before the world, while da Vinci's drawings showing his grasp of anatomy were locked up in a private portfolio for centuries. Vesalius published his great work before he had reached the age of 30.)

75. **Editions of Vesalius' Works.**—Forty-seven pages are devoted to this list of the various editions that have been published of Vesalius' work and of the principal commentaries thereon.

76. **Vesalius' Work in Experimental Physiology.**—Van Rijnberk remarks that Vesalius' fame as the father of modern anatomy has overshadowed his research on physiology, and yet he did considerable work in the line of experimental physiology. The concluding chapter in his great work on anatomy is devoted to the "anatomy of the living," in other words, vivisection. This entire chapter is translated from the Latin here, with its numerous illustrations. The functioning of the muscles, tendons and various organs are discussed in turn. Figure 1 shows his conception of the functioning of the muscles and tendons in maintaining the balance. His total equipment for post-mortem work, vivisection and experimental physiology is shown in Figure 2. The rings at the side of the board and staple and chain at the head are to fasten the animal on the movable board. Van Rijnberk admits that much in this chapter is evidently taken from

Galen, who also did good work in experimental physiology. Vesalius even reproduces, uncorrected, certain manifest blunders in Galen's work. Aside from this, the chapter shows Vesalius as a skilful experimenter, a sharp observer and an excellent leader of a demonstration of experimental physiology. His tests of the functioning of the recurrent nerves are most instructive as also his method for artificial respiration when the chest has been opened—a century and a half before Robert Hook to whom artificial respiration is generally credited. Vesalius further shows insight into the mutual relations between the respiration and the action of the heart. Among the other points he noticed is the lower position of the stomach after a meal. This chapter of Vesalius' work might well serve as an outline for a modern examination in physiology.

77 *Frequency of Occurrence of Single Kidney. (Om Aplasia renis og venae cardinales resistentes.) K. Secher.

78 Progressive Symmetrical Dystrophy of Fat Tissue. (Et nyt Tilfælde af lipodystrofia progressiva.) V. Christiansen.

77. **Single Kidney.**—Secher describes the necropsy findings in a child without any left kidney or ureter, but the suprarenal gland on that side was unusually large. The genital organs were also asymmetrical. Since Ballowitz published in 1895 his compilation of 213 cases of single kidney, other cases have been reported, bringing the total to about 300. Secher remarks, however, that these figures are misleading as in many of the cases the distinction between total aplasia and atrophy of the kidney has not been made clear. The kidney was single in 7 of the 8,150 cadavers he has examined, that is, once in every 1,164 cases. According to the records, this occurs twice as often in males as in females, and it is the left kidney that is usually the missing one. The abdominal vessels and genital organs generally display more or less deformity in such cases. In the case reported in detail the heart was exceptionally large, which possibly may have some connection with the very large size of the left suprarenal.

92 Aseptic Entero-Anastomosis. (Forslag angaaende en aseptisk Metode til Fremstilling af Anastomoser i Fordøjelseskanalen.) H. S. Biilmann.

91. **Disease in the Thyroid Gland.**—Nørregaard states that a tendency to goiter is frequently overlooked as it is much more common than generally supposed, especially in women. In a tuberculosis sanatorium Stein found among 1,283 tuberculous women 29 with exophthalmic goiter and 177 with simple goiter in the course of four years. Nørregaard reviews his own experience with 35 cases. One was in a boy; the rest were all women. A hereditary tendency to disease of the thyroid was marked in a number of his cases, the abnormal thyroid manifesting itself in different ways in various members of the family. These families are inclined to be nervous and restless and there were 14 insane or feebleminded in the family histories of his 35 cases. He says he does not know of any special study of the thyroid by an alienist, but he is convinced that systematic research of this kind among the insane and feeble-minded would bring to light a number of interesting facts.

His own experience has demonstrated a close connection between thyroiditis and tuberculosis and also between thyroiditis and cancer, especially cancer of the breast. Adenoid vegetations and tonsillitis are also unusually prevalent among persons with simple or exophthalmic goiter. Detailed analysis of his 35 cases suggests that the thyroiditis develops from some focus of infection elsewhere, most often in the tonsils. Comparative anatomy shows a direct communication between them in some animals, and Weglowski found traces of a communication in 30 per cent. of 153 cadavers examined, including fetuses and the elderly. Nørregaard cites J. H. Johnson's report of several cases of exophthalmic goiter in which a cure was realized by direct treatment of the lingual tonsils. He always makes a point of direct treatment of the throat in all cases of thyroid disease, supplementary to the thyroid treatment. The results have been good in many instances but of course it is impossible to tell how much of the benefit was due to the treatment of the tonsils or adenoids. The chief danger that threatens persons with disease of the thyroid is derangement of the heart or mind, and cancer, but one of his patients is now over 80.

REORGANIZATION OF CLINICAL TEACHING

A COMPILATION OF REPORTS OF A SPECIAL COMMITTEE, PRESENTED BY THE CHAIRMAN [*]

VICTOR C. VAUGHAN, M.D.
ANN ARBOR, MICH.

Recognizing the need of a thorough reorganization of clinical teaching in this country, a year ago a special committee of ten prominent physicians of the United States and Canada was appointed by the Council to prepare reports which would serve as a basis for a general discussion of the subject at this conference.

In order to facilitate the work, a meeting of the committee was held in Chicago, December 28, 1914, at which individual reports were made. After a thorough discussion, the bounds were fixed within which the members were asked to confine their treatment of the subject in written reports which were to be sent in. It must be understood that the following is a compilation from these reports and is not the final report of the committee. This compilation touches on many of the problems which should be given thorough discussion before any final recommendations are made. In the discussions at this conference, a special effort has been made to have all points of view represented, and these discussions will be of great assistance to the committee, which will make its final report later.

FROM THE INDIVIDUAL REPORTS

In considering the reorganization of clinical teaching in the medical schools of the United States, it is necessary to keep in mind that any standards suggested should be of sufficient rationality that they may be adopted by all the medical schools of the country which have sound reasons for existence. It is necessary to remember also the educational and financial status of the communities in which the various medical schools are situated. Certain standards may be set forth for adoption in the immediate future, while more advanced standards may be suggested to provide for evolutional improvements, to be adopted at certain fixed periods in the future—just as was done in 1905 with regard to admission requirements and full-time teachers in the laboratory departments.

In advising a standard of clinical organization, there are certain essentials which must be considered:

1. *Adequate Hospital and Dispensary Facilities.*—A properly equipped hospital is an essential part of the first-class medical school, which should have absolute control of the medical management and beds. A small hospital so controlled by the medical school has a much greater educational value than a large hospital in which clinical teaching is embarrassed by political or other disturbing factors.

A clinical class (seniors) of one hundred students or less should have a hospital of a minimum of two hundred beds. This minimum cannot well be lowered, because otherwise there will not be the essential variety of patients from which selections may be made. There should also be an outpatient department of at least ten thousand patients, or 50,000 visits annually.

With three main departments, the 200 bed hospital would afford 75 beds for general medicine, including neurology, pediatrics and dermatology; 75 beds for general surgery, including sub-departments of the eye, ear, nose and throat, genito-urinary diseases and orthopedics; and 50 beds for obstetrics, including normal infants and gynecology. This minimum bed hospital for one hundred students could, with advantage, be doubled or trebled for the same number of students by the schools which could financially afford it.

If the medical school cannot build and endow its own hospital, it should establish a relationship whereby some hospital already built and in operation may be attached to its teaching equipment. Such a hospital should be in close proximity to the medical school, and should possess the necessary auxiliary departments, to-wit: A clinical laboratory, a Roentgen-ray department, a bacteriologic laboratory, a laboratory for metabolic investigation (physiologic chemistry), and space for the instalment of apparatus for investigating cardiovascular diseases and the organs of special sense. The dispensary should include all the departments of medicine and surgery, general and special, and should be in intimate and harmonious connection with the wards in the hospital, to which may be referred patients whose diseases or injuries cannot be managed satisfactorily in an ambulant service. In each such hospital, or at least in the outpatient service, there should be a fully organized social-service department.

---

[*] Read at the Eleventh Annual Conference of the Council on Medical Education of the American Medical Association, Chicago, Feb. 16, 1915. The discussion of this paper appears under Society Proceedings, this issue.

[*] The committee consists of Dr. Victor C. Vaughan, Chairman, President of the American Medical Association, Ann Arbor, Mich.
Dr. George E. Armstrong, Professor of Surgery and Clinical Surgery, McGill University, Faculty of Medicine, Montreal, Quebec.
Dr. Frank Billings, Professor of Medicine, Rush Medical College, Chicago.
Dr. John G. Clark, Professor of Gynecology, University of Pennsylvania, School of Medicine, Philadelphia, Pa.
Dr. Harvey Cushing, Professor of Surgery, Harvard University, Medical School, Boston, Mass.
Dr. George Dock, Professor of Medicine, Washington University, Medical School, St. Louis, Mo.
Dr. John M. T. Finney, Professor of Clinical Surgery, Johns Hopkins University, Medical Department, Baltimore, Md.
Dr. Samuel W. Lambert, Dean and Professor of Clinical Medicine, Columbia University, College of Physicians and Surgeons, New York City.
Dr. William J. Mayo, Rochester, Minn.
Dr. George E. de Schweinitz, Professor of Ophthalmology, University of Pennsylvania, School of Medicine, Philadelphia, Pa.

For adequate clinical teaching in obstetrics and gynecology, of the beds assigned for this purpose (preferably 100), two-thirds should be devoted to obstetrics and one-third to gynecology, either under one roof or in separate departments. In addition to this intramural hospital service, a dispensary in direct charge of the teaching staff should be equipped for instruction in the diagnosis and treatment of ambulatory conditions, which make up the routine work of the physician's office practice.

For teaching the specialties, such as ophthalmology, otology and rhinolaryngology, large ward accommodations are not so essential, since satisfactory instruction is easily accomplished in the outpatient departments of these specialties; some beds, or, better, small special wards, however, are necessary. For example, in ophthalmology, from twelve to fourteen beds should be provided, and an equal number should be provided for otologic and rhinolaryngologic patients. An adequate ophthalmic dispensary service, for classes of from 75 to 100 students, should command not less than from 1,500 to 2,000 new patients yearly, or approximately from 7,500 to 10,000 visits.

2. *The Necessity of Adequate Financial Income for Good Clinical Teaching.*—That each clinical department of a medical school should have an adequate endowment, or receive a fair proportion from the general budget, is obvious. Each must have sufficient provision for teachers, technicians and janitors, supplies, new apparatus and books. The latter may be available through a general library; but it should be possible for the clinical departments to get all books, charts, diagrams and other similar teaching material as promptly as possible. It is difficult to make a definite budget that can be immediately applied. Certain general principles seem clear. The head of the department should have an adequate salary, though not larger than that of the heads of other departments. More important than the salary of the heads seems the need of having adequate salaries for those next in rank, that will enable them to be independent of practice. Such salaries would range from $2,500 to $4,000 or $5,000. These men would then have positions somewhat like a German extraordinarius or primarius, except that instead of getting their income from students' fees and consultation cases, they would get it from the university. Even small schools should have one such man; larger schools would need two or three. They should be kept in the school as long as they are useful, but encouraged to migrate when they get good offers, so that they would rarely reach the maximum salary. Next to these men, there is need for from two to five or six well-trained men who could carry on clinical work including research, and teach. They also should have salaries that would permit them to be independent of practice, say, from $1,500 to $2,500. Below these would come residents and assistant residents, getting respectively from $500 to $1,000, or from $300 to $500 a year and their keep. There should be enough technicians to care for the laboratories and part of the laboratory work, such as preparing dyes and reagents, photographic work, section-cutting and other routine work. The budget should provide for an adequate stenographic force, for supplies and for new equipment. In developing satisfactory clinical staffs, it may be necessary to take young men and train them, beginning with small salaries, because men of desired experience (worth from $1,500 to $3,000 a year) are sometimes difficult to obtain.

As the full-time professorship plan is now on the proving ground, and, with one exception, there is to-day no medical school so financially situated as to institute the plan, a budget to provide for it would be prohibitive. For a medical college having a clinical class of two hundred students (one hundred juniors and one hundred seniors), the minimum clinical annual budget should be from $75,000 to $100,000.[1] This sum may be apportioned approximately as follows: To medicine and its subdivisions, from $30,000 to $40,000; to surgery and its subdepartments, from $30,000 to $40,000; and to obstetrics and gynecology, from $15,000 to $20,000; and this budget unit could be doubled when possible without extravagant expenditure. The total budget also will vary greatly, depending on locality and other conditions. The same amount of money, for example, would go much further in Ann Arbor than in New York City.

The organization for the clinical faculty for the school and hospital unit and the disposition of the budget may be illustrated:

1	Chief or Head of Department	$2,500	to	$5,000
1	Associate or Assistant Clinician in Hospital	1,250	to	2,500
1	Associate or Assistant Chief of Clinical Laboratory	1,250	to	2,500
1	Associate or Assistant Chief of Outdoor Department	1,250	to	2,500
1	Resident	600	to	1,200
4	Interns			
1	Associate or Assistant in charge of Research Lab.	1,250	to	2,500
1	Biochemist	2,000	to	2,800
33	Senior Clinical Clerks			
	Stenographers, artists, etc.	3,000	to	3,000
	Dermatology, Head and Assistants	2,500	to	5,000
	Pediatrics, Head and Assistants	2,500	to	5,000
	Neurology, Head and Assistants	2,500	to	5,000

The subdepartments would have the cooperative aid of the resident, the interns and those in charge of the outpatient, laboratory and research departments.

The organization and disposition of the budget of the surgical and obstetric departments would be practically the same in principle with differences in details.

3. *The Place in the Curriculum to Begin Prescribed Clinical Instruction.*—Most schools are still on a four-years' basis, though the tendency is in the direction of adding a fifth year for obligatory hospital experience. On the four-year basis, it has been found that two years are insufficient for the proper and effective presentation of the clinical branches, which have grown apace and have become increasingly difficult and complex. Much of this difficulty will doubtless be obviated, however, by a careful organization of the clinical departments. Again, two years' time is not too much for teaching anatomy, physiology, biochemistry, etc. A course in physical diagnosis on the normal individual, and perhaps a corresponding preparatory course in surgery, may well be placed in the final semester of the second year. This change seems advisable, since, with the technic acquired, the student may take up the clinical work in the third year with greater profit. It is also advisable because it serves to bridge the gap formerly existing in the student's mind between the preclinical and the clinical courses—a gap accentuated by the intervening long summer recess.

The student should begin clinical work in his second year with practical exercises in the study of physical signs and their relation to symptoms and to pathologic processes. This can be done best in class room and laboratory, on normal subjects or with patients from the outpatient dispensary service. The student should then take up a careful reading of complete text-books of medicine and surgery under personal weekly reviews with instructors, who should in conferences discover what progress the student is making in this work. In his third year, and coincidently with this theoretic study, he should continue his practical work in a dispensary and at the bedside, and should be given, in formal clinics and lectures, the most recent ideas as well as the long-established facts of the practice and theory of surgery and medicine. Instruction in obstetrics and gynecology should be finished in the third year with the exception of certain practical courses usually best given early in the fourth year. The courses in ophthalmology, otology and rhinolaryngology should begin and be finished in the third year, especially if a satisfactory departmental coordination of teaching can be established. In his fourth year the student should be prepared to follow and be a factor in the ward service of a teaching hospital.

---

[1] This does not include cost of maintenance of hospital and dispensary.

If the arrangement for beginning clinical instruction in the sophomore year is adopted, graduates of some universities which offer the so-called combined medical course leading to an A.B. degree, and which give only the first two years of the medical course, will enter handicapped in so far as their preliminary course in physical diagnosis and the preparatory course in surgery are concerned, unless a certain amount of dispensary and hospital material may become available at those schools.

4. *Use of the Dispensary.*—An abundance of outpatient clinical material is one of the most valuable teaching assets of the medical college. Thus far, however, its value has not been appreciated, nor has the material been used to nearly so good a purpose as is possible. The dispensary material should be used for the instruction of undergraduates and for the clinical and other researches of the attending staff. It is best used for students in the second year for teaching physical diagnosis, and in the third and fourth years in internal medicine and in the medical specialties. Its greatest, and perhaps most neglected, use is to instruct third year students in the routine of history taking and fourth year students in the therapeutics of the lesser medical and surgical ailments. The dispensary service should be intimately connected with the ward service in every department. The obstetric material should be used in the third year for diagnostic purposes only, the practical care of the lying-in patients, both in the hospital and in private homes, being reserved for the fourth-year students. The gynecology dispensary material also is best used in the fourth year. For certain of the specialties, such as ophthalmology, otology and rhinolaryngology, outpatient clinical material is highly essential, and should be utilized for sections of from six to ten students, each section in charge of an instructor or demonstrator. The essentials in diseases of the eye, ear, nose and throat can be taught readily and with great thoroughness in the dispensary clinics.

5. *The Organization of the Hospital Units.*—In planning the construction of a hospital, the bed unit per ward should be considered. This bed unit depends on the number of beds to be assigned to each attending nurse. For acute cases four beds can be taken care of by one nurse; for more chronic cases six beds may be assigned to a single nurse. This makes 24 beds as a convenient ward unit; such a ward can be used either for chronic or acute cases. As many such units may be added as needed, varying with the size of the hospital. A service for a minimum-sized teaching hospital, one of approximately 200 (actually 192) beds can, therefore, be divided into eight such units of 24 beds each, four units (96 beds) each for the medical and surgical services. More satisfactory, however, would be a hospital of 300 (actually 288) beds, providing 150 (actually 144) beds each for the medical and surgical services. Each of these services could then be easily divided into three equal subdivisions of 48 beds each. Taking either the medical or the surgical service as an example, the personnel to direct and care for such a service would consist of the professor in charge, who should be the director of the service; three first assistants and six second assistants. One first assistant and two second assistants should be in charge of each third of the service. Under this staff, who do not live in the hospital, there should be a resident staff, to consist of resident physicians, at least three in number, who should serve with indefinite periods. These residents should be the direct overseers and instructors of the students on the clinical clerk service and also of the intern staff. There should be two interns to each service of 48 beds, serving for one year, in two grades of six months each—junior and senior. And, finally, there should be twenty-four or thirty clinical clerks, all fourth-year students, assigned to the service, eight or ten being designated to each subdivision. In addition, there might be voluntary assistants serving without pay, who would be doing special research work within the service both in the wards and in the laboratories, in which work the residents and also the first and second assistants could take part, although the regular staff should be especially concerned with the teaching of the students of the undergraduate school. The first and second assistants, in addition to their hospital work with the fourth-year men, should take care also of the third-year theoretic and practical instruction and of the second-year preliminary work; and at least one of the second assistants should have charge in the dispensary of the hospital and link that important organization to the ward service in the outpatient department. There should be extern assistants of sufficient number to take care of the ambulant patients.

The subtraction of one of these units from the above estimate would be no special hardship, but the addition of one or more, particularly of two units, would probably necessitate an entire duplication of a department in medicine and surgery, for it is doubtful if a single director should be asked to take charge of more than 150 beds. It would seem, therefore, that a partial duplication of the educational unit would entail an expense out of proportion to the educational results obtained.

The organization of special departments, such as that of ophthalmology, otology and rhinolaryngology, necessarily depends on the number of students enrolled, on the amount of money available for the departmental expenses and on the number of hours assigned to it in the curriculum. With classes of from seventy-five to one hundred students, there should be in each of these departments a professor, or head of the department, an assistant professor, and not less than three or four instructors. The instructors in the diseases of the eye, ear, nose and throat should have received a general hospital training in medicine and surgery, and should have devoted themselves to the diseases under consideration for a considerable period. Each should have had a full course, for example, in ophthalmology or otology, with at least one year's work in a clinic, in addition to the preparatory training in medicine and surgery. They should be in a sense regarded still as advanced students, a large part of whose compensation consists in the opportunities for higher education, and while they are training the students who are assigned to them for instruction in the outpatient work, they are training themselves for more advanced positions.

A serious deficiency in the majority of teaching hospitals is the wide separation of the departments of a given unit. The laboratories, research rooms, so far as an investigation applies directly to the living patient, the history rooms, working library, residents' rooms, auditorium, and, indeed, every part of a clinical unit which makes for efficiency should be housed under one roof. Cooperation between departments should be encouraged so far as it relates to the larger problems and principles of medicine, but each department should be so completely constructed and the working staff so well provided for, in direct touch with the wards, that every detail of investigation and treatment may be conducted without reference to any other department. As now constituted the ward of the average hospital transmits its material for routine investigation to large laboratories more or less remotely removed from the wards. Often a perfunctory report is returned from a laboratory assistant, who may know nothing of the clinical problem at stake—a report, therefore, frequently not worth the paper on which it is written. A hospital unit should constitute a complete workshop, self-sufficient for all clinical purposes, and independent of all other departments, and under the immediate care of the director and his assistants. The larger problems should be dealt with by departmental conference and close coordination, each clinical chief calling to his aid colleagues in other departments, who may, through their special knowledge, shed new light on questions impinging on his domain.

6. *The Utilization of Students as Clinical Clerks in Hospital Wards.*—The clinical clerk system is the best for training undergraduates in clinical branches, provided their work is properly supervised by a senior resident physician, an instructor, or a demonstrator. This work should be begun as soon as the student has the necessary theoretic and technical training, and experience shows that they may begin as clinical clerks not earlier than in the last trimester of the third year with the three main divisions of (*a*) medicine, including pediatrics, neurology and dermatology, (*b*) surgery and the surgical specialties and (*c*) obstetrics and gynecology, and complete a trimester in each. The undergraduate will finish his general training at the end of the second trimester of the fourth year, and may then go on to more elective work. The student in the ward system learns by doing, by applying the scientific and technical knowledge acquired in the first two years and by receiving further instruction through teachers of various ranks in wards, laboratories, operating-rooms, clinics, and library.

In the obstetric wards the utilization of clinical clerks is most important. The many examinations of secretions, the testing of blood pressure, the regulation of metabolism through clinical tests, the observation and care of the infant, the estimation of the value of the mother's milk, are all so important that clerks should be in constant attendance; indeed it is most desirable that they should be in residence. The assignment of the number of patients to each student must be regulated according to the ward census and the number of students in class. In the wards devoted to the specialties, on the contrary, such as ophthalmology, otology and rhinolaryngology, students as clinical clerks are of very little service. Most of the material in these departments is better used in ward class instruction.

Before serving as clerks, even in the wards devoted to medicine and surgery, the student should have a sufficient knowledge of the specialties to determine the most conspicuous departures from the normal. For example, they should be able to determine the acuteness of vision and the field of vision; to know the method of testing the pupil reflexes, the simpler methods of determining the absence or presence of diplopia and of determining the probable character of deafness.

The period of service as clinical clerks in each of the two chief divisions of internal medicine and surgery should be not less than two, and better, four months' duration. The teaching personnel should consist, in each department, of a directing officer and of instructors to attend to the subdivisions of the class in their theoretic and practical work. The equipment should include a hospital with a dispensary service, in addition to the necessary laboratories, class-rooms and library. The hospital must be large enough to supply a sufficient number of clinical beds so that at least five, six, or eight beds could be assigned to each student for at least one-third of the college year. This final course of instruction as clinical clerks should consist of placing each student in charge of his quota of beds and making him a part of the hospital service and placing on him the responsibility for accurate observation and careful records. A strict accountability from the students can be secured only by a resident supervisor who has direct contact with their work and with the wards.

The hospital necessary to provide for clinical clerks must be large enough to accommodate the students enrolled in the school with which it is connected, or, in other words, the number of students enrolled in any medical college should be limited according to the size of its teaching hospital. If six beds were assigned to each clinical clerk for an entire year, a medical service of 150 beds would be necessary to accommodate 25 students; whereas, the same number of beds would accommodate 30 students for the entire year if 5 beds were assigned to each. Since it is estimated that each student should devote one-third of his year to each of the three services, it follows that a school averaging from 75 to 100 students in its graduating class would require a hospital service of approximately 150 medical beds and approximately 150 surgical beds, with additional provision for obstetrics and gynecology. A service of 150 beds is as large as should be under the direction of a single professor of medicine or surgery. If this educational unit of, say 100 students, be increased, it would be difficult to properly train them unless the whole hospital unit in medicine and surgery and its teaching force was duplicated. It is apparent, therefore, that a class of more than 100 senior students would entail an expense out of proportion to the results obtained until that class is duplicated, or nearly so.

7. *Utilization of Special and Extramural Hospitals.*—A medical school with a minimum number of beds, an outpatient department and a minimum budget for two hundred students in the third- and fourth-year classes, could and should amplify the clinical instruc-

tion, without additional cost, by affiliation with extramural hospitals, and increase their teaching force by volunteer clinical teachers on the staffs of those hospitals. When such hospitals are not too far from the medical school, and when sufficient teachers are connected with them as a part of a working educational machine, they may be utilized to good effect. Too often the instruction given in these hospitals is of a desultory or superficial character and the student soon loses interest or finds his time so fully occupied by duties in the central institution that he ceases to attend the classes. Only by a very close interlocking system under the direct supervision of the dean of the medical school may such instruction be of value.

Almost every community dense enough to justify the existence of a medical school is served by a large number of general and special hospitals. The use of such hospitals is desirable, especially if the school can secure in this way an opportunity for its students to study the types of diseases which are not usually seen in the active general hospital service. The chronic diseases of the joints and of the nervous system, the advanced stages of tuberculosis and of the alterations in physiology of the aged, as well as the care and feeding of healthy infants, can best be seen in the homes and nurseries devoted to such work rather than in general hospitals. Then there are the special hospitals for maternity cases, eye and ear infirmaries, orthopedic hospitals and the like, where certain classes of patients may be found in greater abundance than at the general hospital. The system of education by service as clinical clerk necessarily takes a student away from his school routine to a certain extent and lends itself readily for visits to such institutions even at a considerable distance from the school. It is possible, therefore, to use extramural and special hospitals for ward classes and in the service for clinical clerks, but, of course, the school should control the appointment of the instructors in charge of that work.

Only hospitals under complete university control should be used for undergraduate teaching. Other hospitals, so-called extramural hospitals, may, with advantage, be maintained for the training of teachers, for keeping up a spirit of emulation among teachers, for illustrating features of disease not often seen in general hospitals and for the instruction of graduates. As many extramural hospitals as possible should be brought into affiliation with the medical school, to provide for the development of graduate work, which now needs to have careful consideration. Hospital trustees, as well as the public generally, are beginning to realize that active educational relationships with medical schools are of the greatest benefit to the hospitals, the patients and the public.

8. *Departmental Coordination of Teaching.*—That there is need of greater coordination not only between the various clinical departments, but also between the clinical and laboratory departments is quite apparent. Of equal importance with deciding the place in the curriculum where the various clinical branches shall begin and recommending to the first-class medical schools the adoption of a uniform plan in this respect, is this question of departmental coordination of teaching. Too often it would seem that the relationship of a student to certain branches of his instruction is that of a school child who says, "I have finished such and such a study." Like the child, he says, "I have finished anatomy, histology, embryology," and literally puts it away until he must hurriedly resurrect it prior to a state board examination. This could be avoided if there was a coordination of the courses, step by step, the professor of physiology, for example, or of chemistry, emphasizing the practical relationship of his branch to the instruction in the clinical departments. So, also, whenever it is possible it would seem wise that students should be able to attend instruction at closely related periods of time in subjects that are intimately connected one with the other, for example, the anatomy and the physiology of the circulatory apparatus, and the physiologic action of various remedies on this apparatus.

Another matter, and one of great concern to medical students, to use a homely phrase, is how to decide when doctors disagree, and too often the statements of teachers conflict. That any teacher should be forbidden an expression of individual opinion in the course of his instruction would naturally not be tolerated, but the opposing view, if there is an opposing view, must be fairly stated, and consensus of opinion clearly given. Such "conflicts" can be avoided by frequent conferences either between the heads of the departments, or between the head of a department and his corps of instructors. In like manner, the repetition of courses can be prevented by similar conferences, and also by a rule that the head of each department shall file in the dean's office, at the beginning of each semester, a schedule of the courses his department proposes to offer.

There is marked advantage also in the use of combination courses, like those inaugurated at McGill and Harvard, in which the professors of medicine and of pathology unite to demonstrate ante-mortem diagnoses and post-mortem findings. Similar combinations between the departments of surgery and anatomy in the study of fractures and dislocations, and of physiology and medicine in the study of the heart and circulation, have been given in other schools.

In order that students shall realize the importance of the "head specialties" (eye, ear, nose and throat) in their study of general medicine and surgery, departmental coordination is of particular advantage. Thus, for example, the teaching of ophthalmology should be in close relationship with that of physiology (the physiology of vision); with that of neurology (ophthalmic neurology); with that of clinical medicine (medical ophthalmoscopy); with that of surgery (problems of increased intracranial tension, ocular interpretations of spinal and cerebral lesions). An excellent plan is suggested in one report, which permits the head of the department of ophthalmology to invite the heads of the departments of clinical medicine and surgery to give portions of the lectures and demonstrations, which in the last-named branches must necessarily be concerned with the results of ophthalmic examinations. The same plan would apply to other specialties.

In general, all laboratory teachers will have their own work and their own problems, though many of the latter will be purely scientific. At all times the clinical workers should be sure of cooperation and assistance from the laboratory staffs. It would be desirable if they could at times move into the chemical or physiologic laboratory, or even that of physics, in order to become more familiar with other work, or to obtain suggestions as to how they may attack some fundamental problem. Our long and rigid courses and the fact that all our vacations come at the same time prevent this practice from being as much in vogue as it is in Europe.

9. *Limiting the Practice of Clinical Teachers.*—The recently formulated question of limiting the practice of clinical teachers deserves careful consideration. The members of the committee are unanimous in expressing a sympathetic interest in the educational experiment of providing full-time clinical professors in medicine, surgery and pediatrics now being tried out at the Johns Hopkins Medical School, an institution having such admirable facilities for it. In fact, the principle that the practice of clinical teachers should be restricted appears to have general acceptance. In determining to what extent that practice should be limited, there are two extremes somewhere between which it is possible to construct a rational scheme. On the one side is the whole-time requirement as adopted at Johns Hopkins, and on the other side is the condition in some medical schools where clinical teachers are so busy with their private practice that their teaching is bady neglected. Opinion is by no means unanimous that the whole-time requirement is ideal, but even if it is ideal, such a requirement could not rationally be advised at present owing to the fact that so few of the medical schools are adequately financed to put it into effect.

On the other hand, it is imperative that we get away from the other extreme. An extensive time-consuming private practice, with the minimum of teaching responsibility, must give place to the teacher whose chief business is to instruct medical students, who chooses the work because he loves it, and who is qualified by education and by personal experience in experimental work to be a productive teacher. Given such teachers, the limitation of their practice will take care of itself. A matter of the highest importance is to build up a system of organization that will develop for the future the best clinical teachers. Is the best scheme one that will demand a restriction of private practice to hospital consultations, or should private practice be prohibited entirely? Is a certain amount of private practice essential to develop the best clinical teachers? Is some private practice by clinical teachers essential to keep medical education in sympathetic touch with the human side of medical practice? Will the placing of clinical chairs on a full-time basis result in a gradual separation of medical teachers from perhaps some of the most vital problems of active medical practice? These are some of the questions which should be considered in the discussion of this subject.

IN CONCLUSION

Whatever may be said regarding the practicability of limiting the practice of clinical teachers, the other propositions dealt with in this paper have to do with improvements which are well within the reach of the majority of medical colleges. To construct a reasonable working standard for immediate adoption and another more ideal standard for adoption sometime in the early future, is the chief function of this Committee on the Reorganization of Clinical Teaching. This committee will doubtless receive much valuable aid in its task from the discussions at this conference.

The Primal Aim.—For the state as for the individual, health is the first postulate of prosperity and prosperity should be the first object of scientific government.—Ronald Ross, "The Prevention of Malaria."

THE UNIVERSITY AND HIGHER DEGREES IN MEDICINE *

GEORGE E. VINCENT
President, University of Minnesota
MINNEAPOLIS

The university has hardly assumed responsibility for one problem of medical education before it finds itself confronted by other demands in the same field. There were good reasons why institutions of higher learning should undertake the conduct and standardizing of undergraduate training in medicine. The proprietary medical schools of the older type had rendered valuable pioneer service but were reaching the limits of their efficiency. Large resources of laboratory, clinic and endowment were needed to supply proper facilities for medical education of the newer type. The university was in a position to do much if not all that the situation demanded. Modern medicine is wholly dependent on the fundamental sciences of physics, chemistry and biology. The university was already equipped to furnish the necessary preparation in these departments. There was obvious economy in an oragnic connection between medicine and other university disciplines. So, too, many subjects less fundamental but distinctly ancillary were already included in the university curriculum and could be used to strengthen and enrich the medical courses. Furthermore, the general atmosphere of investigation and professional teaching which characterizes the university environment was singularly favorable to the proper development of research and instruction in the medical sciences.

In the university community it was also easier to foster the altruistic ideals which ought to guide and inspire the medical profession. Important, too, was the fact that the university stands as a disinterested social agency, aiming primarily, not at offering special privileges to individuals, but at rendering service to the public. By creating standards and applying tests it tries to protect the community against incompetent and unscrupulous exploiters of public credulity and confidence. It was right and inevitable, therefore, that the university should assume chief responsibility for the organization and standardizing of undergraduate preparation for the medical profession.

The rate at which modern science is developing is almost disconcerting. This is conspicuously true of the progress of medical science and technic. This growth is, to be sure, beneficent, but from an administrative point of view its rapidity and the insatiable demands which flow from it have a touch of malignity.

The undergraduate curriculum cannot begin to include the new knowledge. Specialization here, as in many other fields of human investigation and experience, is not to be avoided. From the starting point of a fundamental general training men must devote themselves to differentiated subjects of inquiry and an appropriate technic. Out of this situation and the consequent needs of the profession come certain insistent demands. Able practitioners more and more feel the necessity of keeping abreast of the newer developments in medical science. It is of prime social importance that these men should be afforded every available opportunity.

---

* Read at the Eleventh Annual Conference of the Council on Medical Education of the American Medical Association, Chicago, Feb. 16, 1915. The discussion of this paper appears under Society Proceedings, this issue.

There are other practitioners whose professional education has been defective. These men are desirous of making up lost ground and bringing themselves nearer to the better standards of to-day. Both individual need and social welfare suggest the value of aiding men of this class. Again, an increasing number of medical graduates appreciate the necessity of making a thorough preparation for a specialty. They require something more than brief and fragmentary courses; they desire continuous, advanced and authoritative instruction as well as opportunities for investigation. Last of all, another group of students who are particularly interested in research and in teaching as careers are seeking thorough preparation and disciplinary training in the best methods of original investigation. Finally, there is a growing public demand for special service and for some way of knowing how to tell the qualified from the pretenders.

The same reasons that led universities to take over undergraduate medical teaching now seem to justify them in trying to meet the other demands which have just been enumerated. There can be no doubt that the university equipment and environment afford the best opportunities for doing these newer things. It is especially important that right standards should be gradually worked out. The university is in a position to create and protect such standards as no independent group can hope to do. These standards, it is true, cannot be formulated over night and enforced on the public. There must be careful study and matured experience, before anything at all fixed or authoritative is promulgated. Yet at the outset certain ideals and tests may be set up as a basis for gradual, well-considered elaboration. The university has at the beginning this advantage: It can provide an existing prestige and give immediate support to any initial requirements that may be agreed on. University social authority may well provide a better basis for public respect for the medical profession and particularly for those types of special expertness with respect to which the public feels the need of standards of appraisal.

The allusion to university prestige should not be misinterpreted. There are other ways in which centers of authority may be created. For example, the newly organized American College of Surgeons is an interesting and significant attempt to create a new social agency of prestige. There is every reason to believe that in time this and similar colleges will exert an important influence.

In the meantime, the universities have a power which may be utilized at once. It may be noted further, that the European war and the conditions which are likely to exist for a long time after peace has been proclaimed afford American universities opportunities so obvious and insistent as to constitute almost obligations to undertake graduate work in medicine.

The brief courses now known as "postgraduate" or "polyclinic courses" suggest the need for what may be called medical university extension. The value of courses of this kind cannot be questioned. It is only when such courses are superficial, and when they are made the basis for certificates and diplomas of a spurious specialism that they become a danger to the profession and a menace to the public. It seems to be agreed that the so-called "postgraduate" and "polyclinic courses" as conducted in certain large cities of the United States have been distinctly useful. If the university is to do its full duty by medical education courses of this character will have to be provided. In doing this the university will be following logically the development of modern university extension. In this field commercialized education must yield gradually to publicly endowed instruction. Correspondence courses afford a case in point. Universities are providing these courses on a university rather than a business basis.

"Short courses," notably in agriculture, have for some time been recognized as an important form of university extension. "Short courses" or "extra courses" in medicine would fit admirably into a plan of medical university extension. Special courses for this purpose will have to be established, for it seems to be generally agreed that the students who desire them ought not to be admitted to short sections or fragments of the regular undergraduate courses in the medical school. University plants are being utilized and university teachers employed in short courses in university extension. The same idea would be applicable to medical courses. Again, a special extension staff might be recruited and local centers organized under university auspices throughout a whole region.

The plan by which instruction of this kind is regularly conducted in forty-eight German cities is full of suggestions. The whole enterprise is centralized in Berlin, but local academies and teaching centers provide a net-work of medical extension throughout a large part of the German Empire. Beginnings of such a plan have been undertaken in Kentucky, and Wisconsin is reported to be contemplating a similar experiment.

In assuming responsibility for medical instruction of an extension type, the university should protect the public and should maintain standards by carefully differentiating between "practitioners' courses," "extra courses," "summer courses," or whatever term may be employed, and courses of an advanced and genuine graduate character. The use of the term "postgraduate" is unfortunate and ought to be abandoned. It is a source of constant confusion. Postgraduate applies to the student and is a time designation; the emphasis is on the *post;* while the word *graduate* has come to describe a kind of advanced work distinctly above and beyond the undergraduate type of instruction. It is to be hoped that some such term as "practitioners' course" or "polyclinic course" may be substituted for the term postgraduate.

The university should also raise the minimum length and improve the character of courses for which any sort of recognition will be given. The university medical school should in every feasible way make its laboratories and clinics accessible to ambitious and intelligent practitioners, but the institution should be extremely careful with respect to any formal recognition which is given to individuals who take advantage of these opportunities. It is the duty, therefore, of the university, to guard conscientiously the issuance of formal certificates of proficiency. The public will not sharply distinguish between such certificates and the diplomas which may be granted for work of a very different character and quantity. Harvard has set an admirable example by announcing that after June 1 of this year certificates will be isued only to students who have spent at least eight months in full time study.

Although universities recognize their obligation to provide "practitioners'" or "polyclinic" courses, they are peculiarly concerned in the development of advanced or truly graduate instruction. Teaching of this type must be tested by the best standards that prevail throughout the graduate school of the university. The instruction should be planned for practitioners or other graduates who can devote at least a year to advanced study. The many American physicians who have been accustomed to spend a year in study abroad represent a group who more and more will look to American universities to provide the opportunities which have heretofore been sought in Europe. True graduate policies will concern themselves most of all with those students who are able and willing to devote a period of two or three years to advanced study and research. Such men would be preparing themselves for specialties based on careful scientific investigation, rather than on mere technical skill. Advanced instruction of this sort would also appeal to those who are interested in the career of investigation and teaching.

One of the strongest appeals which this graduate work makes to the university is the hope that it will increase the supply and improve the training of medical teachers. Is it too much to expect that in the groups of advanced students there will begin to appear that longed-for clinical teacher who will be willing to devote himself to medical investigations and teaching on terms comparable with those on which his laboratory colleagues can be induced to devote their lives to this career? Is there no escape from the idea that all clinical teachers must have training in private practice?

Furthermore, the university would welcome advanced graduate teaching because of its reaction and influence on the medical school as a whole as well as on the graduate school of the entire university. It must not be forgotten that medicine has long since ceased to be a drugging art and has become one of the biologic sciences. The formal recognition of medicine as one of the legitimate subjects of graduate work would have an important bearing on research and advanced teaching in every department of the university.

It is hardly necessary to do more than mention the influence of the graduate work on university hospitals. The clinical material would be more effectively used, and the staff, including the interns, would be stimulated. This would involve better and more intelligent service for the patients themselves.

In planning graduate work of an advanced sort the university must not be misled by analogies with other types of graduate teaching. It would be an unfortunate mistake prematurely to impose on advanced medical instruction a fixed curriculum. Even the undergraduate curriculum has suffered from traditional rather than rational growth. In the words of Dean Blumer: "The growth of most medical curricula has been stalactitic rather than logical, by accretion rather than by selection." The graduate curriculum ought not to be allowed to suffer from this tendency. As a matter of fact the conditions are all against a formal and fixed curriculum. The number of students would not in many cases justify the organization of regular classes and courses. Moreover, the expense would be prohibitive and there would not be enough teachers available. The work, therefore, for a considerable time must be informal and individual, of the apprenticeship type. The graduate students would naturally constitute a corps of men spending the larger part of their time in close personal contact with the leading men of the medical school staff. The work, moreover, ought to involve the development in the student of resourcefulness and individual initiative. He should have, under proper regulation, the fullest possible access to laboratories and clinical material. He should be set problems and held to responsibility. In other words, the work should be conducted in the true graduate spirit rather than in the didactic fashion once traditional, if not appropriate, in the undergraduate courses.

The neccessarily individual character of graduate work in medicine has important implications and consequences. Undergraduate teaching demands class instruction and centralized clinical facilities. Graduate activities must lay the stress on problems, specialized opportunities and leadership in investigation. Graduate students may, therefore, be encouraged to seek men, materials and methods whenever these are to be found, provided only that the direction and oversight of competent investigators can be guaranteed. Various institutions, public and private, can be utilized and credit toward higher degrees or certificates granted for work done under accredited auspices. The University of London and the University of Cambridge recognize in this way certificates from certain cooperative clinics in London. The university should make its object the discovery and organization of all possible agencies for giving graduate students the best opportunities for individual work under the most stimulating conditions.

The social and economic basis for graduate work deserves consideration. The increasing cost of medical education to the student as well as to the university has been frequently challenged. It is asserted with a good deal of force that the body of medical students represents economic selection rather than the survival of the best type of ability. The proposal, therefore, to add two or three years to the period of medical preparation raises serious questions. The pressure on graduates to enter medical practice is naturally strong. When a successful practice has been secured the temptation to maintain this is hard to resist. Nevertheless it is well known that many men, after four or five years of practice, surrender a large part of the advantages gained and spend a year or more in foreign study.

There are other men who seem ready to continue graduate work after taking the first degree in medicine. Some of these men have private means, but most of them can continue only with the aid of a stipend. It seems likely, therefore, that, as in the case of all graduate work, fellowships and teaching assistantships will have to be provided by the university in order to cooperate with the men who are willing to devote so long a time to thorough medical preparation.

The employment of such fellows and assistants is not to be regarded as a device for supporting graduate students at the expense of the undergraduates. In many ways these fellows would be helpful to the younger students, could give individual attention to them and perform a useful function in supplementing the work of the regular staff. The further possibility of discovering and developing special teaching aptitudes in these fellows will be readily apparent.

The University of Minnesota Medical School has made a beginning in establishing teaching fellowships. Such fellowships involve ordinarily an appointment for three years on a stipend of $500 for the first year, $750 for the second, and $1,000 for the third. It is too early to make prediction as to the outcome. All that can be said is that for the present year five or six excellent men have accepted these fellowships; the outlook is distinctly promising.

Graduate medical work ought to have an important bearing, as has already been suggested, on the problem of securing medical teachers; especially in developing a new type of clinical teacher. Heretofore no career other than practice has been open to the men whose special interests were in the clinical field. Teaching with them has been more or less incidental to the practice of their profession. Medical education owes a great debt to hundreds of practicing physicians who have given generously of their time and effort to the building up of medical schools in the United States. But it is recognized that the conditions are changing and that the old plans must yield to new policies and practices. The payment of clinical teachers is one of the most important, as it is one of the most baffling, of the present problems in medical education. The experiment at Johns Hopkins University Medical School and the proposed experiment at Washington University will be watched with much interest. What effect a high clinical salary will have on university administration generally is hard to say. If a large clinical salary is to be regarded merely as a temporary adjustment to existing conditions, the difficulties may not be serious but if such a salary scale is accepted as normal, the effect not only on laboratory investigators and teachers, but on the members of the faculties in law, engineering, and other professional schools will be watched with considerable solicitude by those who are responsible for university budgets. If, therefore, a new type of clinical teacher can be developed who will measure himself, not with successful practicing physicians, but with his colleagues in the university, a great advance will be made in medical education. Certainly the development of graduate work will aid rather than hinder such a solution. This should not be interpreted to mean that the practitioner is to be ultimately eliminated from medical teaching, especially from graduate work in medicine. So far as one can now see, such teachers will always be needed for rounding out the clinical curriculum, and notably for directing graduate work in the various special fields.

The policy with regard to university degrees for graduate work should be conservative. There is danger of putting too much faith in degrees. One must have a good deal of sympathy with those who rebel against formal academic honors. Some one has said: "A degree is a title of dignity, not a badge of proficiency." There is some support for the contention that the degree is neither of these things. The academic world appraises pretty accurately the value of a degree. The degree of Doctor of Philosophy, for example, is not deemed a token of proficient scholarship or of great achievement. It indicates merely that one has become familiar with scientific method, has been given a preliminary apprenticeship in the technic and spirit of advanced work, and has been regarded by a group of scholars as giving promise of ability to do independent and authoritative work. The Ph.D. is a license to undertake a task rather than a guarantee that one will accomplish it. Degrees nevertheless have undoubted value. They are made the basis for academic selection. There is danger no doubt of applying such a standard too rigidly. Nevertheless, to appoint to an academic position a man who has not received his doctor's degree is regarded either as a questionable practice, or as a distinct tribute to the individual's capacity and independent resourcefulness. Moreover, the degree is one of the devices for recognizing and maintaining standards. In the medical field it would be a way of indicating that a medical teacher, for example, must be more than a practitioner. With the introduction of graduate work in medicine it would become the custom not to appoint as a teacher or investigator one who had not done advanced work of the sort which could be recognized by a degree.

There is room for difference of opinion as to the wisdom of multiplying special degrees. In behalf of such degrees it may be urged that they would have a special and distinguishing character that would indicate correctly the type of work for which they were granted. On the other hand, there is danger of misunderstandings and of unscrupulous imitation when the number of different degrees becomes so large that the public is confused. The tendency in academic life seems toward a few well-understood marks of distinction. Such degrees fall into three classes: first degrees, that is, various forms of the Bachelor's degree; second degrees, the several Master's degrees, and third, the degree of Doctor. Here the standard graduate degree is the Doctor of Philosophy. The degree of Doctor of Public Health is ranked with Ph.D. Medical degrees are not quite in accord with academic practice. To be sure, we now have a baccalaureate basis of B.S. for the Medical degree and it is equally true that in length of time the M.D. is nearly equivalent to the Ph.D. So far as academic standards go, however, the M.D., from the graduate point of view, approximates the M.S. It would be convenient if there might be, as in England, the degree of Bachelor of Medicine, to be followed by the degree of Doctor of Medicine, as a higher degree, but it would be quite futile to attempt such a readjustment. It would be repugnant to the general traditions of American life and especially offensive to the medical profession.

If higher degrees are to be granted they should be given only in recognition of full-time work extending over a period of two or three years. In other words, the academic standards for higher degrees ought to be maintained. As to the character of these degrees, it would seem wise to employ Master of Science, Doctor of Science, and Doctor of Philosophy to appraise the different types of graduate work in medicine. These degrees have a well-recognized status and would bring medical graduate work into complete accord with the other graduate work of the university. In case it seemed well to recognize the different specialties, the diploma itself might indicate the particular field in which the work toward the degree had been done.

There is one important reason for using the conventional degrees for recognition of advanced work in medicine. The distinction between laboratory and clinical work would be less sharply drawn than it is at present. This seems to be highly desirable for it is more and more obvious that laboratory work which is not in constant relations with the clinical side is likely to become abstract, academic, and sterile. It is quite true, on the other hand, that clinical work that does not keep close to the laboratory is in danger of tending toward empiricism and mere technic. It would be a great gain if graduate work in medicine and the degrees which were granted in recognition of it could consciously emphasize the importance of keeping the laboratory and the clinical sides in constant and reciprocal relationship.

In conclusion, we may summarize the situation as follows: The university must assume its obligations toward all types of medical education; it must distinguish consciously and carefully between medical extension and genuine graduate work in medicine; it must develop graduate courses in an informal and flexible way so as to utilize accumulating experience wisely, take advantage of all facilities, and avoid a premature conventionalizing of advanced work in medicine. Finally, the university should adopt a cautious, conservative policy with respect to higher degrees; it should aim at coordinating graduate work in medicine with the graduate work of the institution as a whole, and should recognize this work in practically the same way that all types of advanced study are signalized.

COURSES AND DEGREES IN PUBLIC HEALTH WORK *

M. J. ROSENAU, M.D.
Professor of Preventive Medicine and Hygiene, Harvard University Medical School
BOSTON

The educator interested in preparing students for service in public health work must take several factors into account. First of all, the education must be for service. Furthermore, the quality of that service is exacting and of great importance to the community. In order, then, to be satisfactory, the education must be special, yet comprehensive. The saying that the student should know something of everything and everything of something applies here with particular emphasis. The underlying sciences which form the basis of preventive medicine are various, and therefore a satisfactory knowledge of the medical as well as the related sciences is necessary for success in a public health career.

Pehaps the next most important consideration is that the education for public health service may take one of four directions. The public health servant may be teacher, research scholar, technical expert or administrator. A survey of the field of public health work as it exists in this and in other countries will disclose the fact that the successful workers are dedicating their lives to one of these four general subdivisions. Some peculiarly fitted by nature and temperament are teaching the subject; others are sacrificing much to the call of laboratory research; others again are devoting their energies to the technical art of one of the sanitary sciences, while many must be administrators. Occasionally we find a man with special endowments who combines several of these phases and is at once administrator and research student, technician and teacher; but as a rule it will be found desirable if not necessary to place emphasis on one line of activity in order to achieve success—at least to achieve distinction, which currently passes as success. There is much overlapping and interlocking, for often the research student becomes teacher; the technical expert becomes administrator.

With these points in view, the next matter requiring our attention is that since the education is to be for service, it must be practical, but a practical art based on sound science. The only satisfactory practical work done in public health lines is accomplished by those who have a secure scientific foundation. It is pitiful to watch the vain strivings and waste of energy, time and money by public health officers who have an imperfect or incomplete knowledge of the sciences on which their work is based.

This brings us to another important consideration, and that is, that the object of public health work is the prevention of disease. It is impossible successfully to prevent disease without a knowledge of disease. Therefore, the fundamental medical sciences must form the background of a good education for public health service. By this I do not mean the orthodox medical curriculum that has for its object training for the practice of medicine. The practitioner of the art of medicine must make a special study of diagnosis and treatment. When a patient consults a physician, he wants to know two things: First, "What is the matter with me?" and second, "What can be done to relieve me?" The successful doctor then becomes a specialist in the recognition of disease and the use of remedial measures. His object is to cure rather than to prevent. On the other hand, the public health officer is interested more in the mode of spread and methods of preventing disease. The two points of view are quite distinct.[1]

The medical curriculum, already overcrowded, has little time for sanitation and hygiene, much less for vital statistics, epidemiology, public health administration, quarantine, industrial hygiene, sanitary engineering, management of epidemics, rural and dairy hygiene, milk supplies, food adulteration, sewage disposal, water purification, heating, lighting and ventilation, housing, social service work, school hygiene, infant mortality, public health laboratory methods, and a number of other subjects on which an efficient health officer must be well informed.

Public health work is therefore becoming, in fact, has already become, a separate profession. It has split off from medicine just as medicine long ago split off from the priesthood. Public health service, as a career, must be made an end in itself. It is often difficult and sometimes impossible to bend the physician into a health officer. The ordinary medical training does not qualify a person to be a health officer any more than the training suitable for public health service would qualify a man to practice medicine. Sanitation, then, has become more than a specialty; it is a profession.

The time has long gone by when the physician can spend a few hours from his busy day to look after the duties of the health office. The situation demands the entire time and energy of those who consecrate their lives to the public welfare. In order to attract capable men to the new profession, it is important that the health officer should have an assured tenure of office with adequate pay and freedom from politics.

These facts are stated in order to throw force into my contention that special degrees should be provided

---

* Read at the *Eleventh Annual Conference on Medical Education of the American Medical Association*, Chicago, Feb. 16, 1915. The discussion of this paper appears under Society Proceedings, this issue.

[1] The modern practitioner of medicine is fast adding prevention as one of the tools of his equipment. The future student of medicine will make a study of health and how to maintain it, as well as a study of disease and how to cure it. However, the point of view of the practitioner of medicine is personal and particular, while the point of view of the sanitarian is communal and general.

for those who qualify for public health service. In this way the fundamental distinction between the health officer and the physician will be borne into the consciousness of lay and professional minds.[2]

A school for health officers in a university organization should occupy a position as separate as that of the medical school, the dental school, the engineering school or the law school. A school for health officers needs a separate faculty, but also needs cooperation with other schools in the university. Thus it needs sanitary law from the law school, sanitary engineering from the engineering school, oral prophylaxis from the dental school, the medical sciences from the medical school. A school for health officers, in fact, must reach out more widely than the resources of any university. Thus, it needs the contagious disease hospital; it needs the city board of health, the state department of health and the federal Public Health Service, for instruction, for inspiration and for opportunities that lie without the bounds of any university. A school for health officers also interlocks with many private and semipublic philanthropic organizations.

All this is a far cry from the practice of medicine, and emphasizes the point I wish to make, that the public health officer needs a separate and special training and should have a separate and special title or degree to designate his special qualifications.

The commissioner of health of a large city cannot be qualified in all the sanitary sciences. He cannot be an expert diagnostician, a good statistician, a competent engineer, a skilled laboratory technician, a capable sanitary lawyer as well as a good administrator, yet he must know something of all these. The commissioner of health of a large city has a corps of specialists to help him in each of these separate fields. On the other hand, the health officer of the small community must be a Jack of all trades. The great point here is that the latter shall be qualified to know his limitations and be ready to call on experts who are furnished by the state and government to assist in troublesome, novel or particularly dangerous situations. To discuss this phase of the subject would carry us far afield; but the facts are brought out here to show that there is need of several kinds of degrees in public health work, such as certificates, diplomas and doctorates.

The certificate or diploma in public health should be used to designate those who have the minimum training believed necessary to carry on public health work. This means at least four years of special study equivalent to college grade; while the doctor of public health degree should be limited to those who have longer training and have in addition carried on original research in some branch of sanitation and hygiene.

How the problem is met may perhaps best be approached by describing a special instance. Permit me, therefore, to tell you how Harvard University has endeavored to solve the problem. At present, the certificate in public health (C.P.H.) and the doctorate of public health (Dr.P.H.) are given in Boston. The certificate in public health is issued by the School for Health Officers of Harvard University and the Massachusetts Institute of Technology, while the doctorate of public health is one of the higher degrees offered by Harvard University.

SCHOOL FOR HEALTH OFFICERS

The School for Health Officers is an enterprise conducted by Harvard University and the Massachusetts Institute of Technology acting in cooperation through an administrative board appointed for this purpose by both institutions. Prof. William T. Sedgwick is chairman of the administrative board, Prof. G. C. Whipple is secretary, and Prof. M. J. Rosenau is director of the school.

The object of the school is to prepare young men for public health work and especially to fit them to occupy administrative positions as health officers, or members of boards of health, or sanitary agents, district health inspectors or technical experts of health organizations.

To this end, lectures, laboratory work and other forms of instruction are offered by both Harvard and the Massachusetts Institute of Technology and by special instructors from national, state and local health agencies. The School for Health Officers also enjoys close cooperation with the Harvard School of Tropical Medicine, so ably presided over by Prof. Richard P. Strong.

The primary object of the School for Health Officers is to provide the scientific groundwork in the sanitary sciences which underlies efficient health administration. The country needs leaders in every community fitted to guide and instruct the people in the art of hygienic living; qualified to direct the expenditure of energy, time and money in public health work into fruitful channels, and able to initiate plans to meet novel conditions as they arise.

The requirements for admission are practically the same as those for Grade A medical schools, that is, two years of college work including physics, chemistry and biology, French and German. Such students are then required to spend not less than two and usually three years in the School for Health Officers in order to get the certificate in public health (C.P.H.).

Students, of course, may be admitted to advanced standing; graduates in medicine of recognized schools as well as bachelors of science, or biology and public health, of the Massachusetts Institute of Technology, who are likewise admitted on their records, may achieve the certificate after one year's work. Candidates for the certificate are not required to have the medical degree, but must have credits in the fundamental medical sciences. While the medical degree is not a prerequisite for the certificate in public health, candidates are advised to get the medical degree before specializing in public health work. Experience teaches that preferment for employment and advancement to the higher positions come more readily to those who have the medical degree.

The certificate in public health is not granted unless the candidate has satisfactorily completed courses in the following fundamental subjects: anatomy, physiology, pathology, bacteriology, biologic chemistry, sanitary biology, preventive medicine and hygiene, demography and sanitary engineering.

Furthermore, every candidate for the certificate in public health must make a sanitary survey of some city or town and submit a report on it. Special emphasis is laid on this sanitary survey on account of its practical importance.

The courses available in the School for Health Officers are not restricted to those stated in the catalogue, but may include subjects in any department of Harvard University or the Massachusetts Institute of

---

[2] At this point it should be made clear that there is a distinction between the medical officer of health and the health officer, and it should be remembered that it is only the latter of whom we are now speaking, for the country needs health officers.

Technology, provided they are in harmony with the objects of the school. Certain special courses are given by instructors not otherwise connected with either institution, and practical work is taken in city, state and national health departments and in the hospitals of Boston. All such work in each instance is conducted under suitable supervision and restrictions. At the completion of his course, every candidate is required to submit to a general oral examination by the administrative board in order to obtain the certificate in public health.

DOCTOR OF PUBLIC HEALTH

This is one of the higher degrees offered by Harvard University. It corresponds in certain particulars to the doctorate in philosophy. To obtain the doctor of public health degree (Dr.P.H.), the candidate must have a satisfactory knowledge of the medical sciences as well as the related physical and biologic sciences that form the basis of preventive medicine. Candidates for the degree of doctor of public health are advised first to take the course leading to the degree of M.D.

Graduates in medicine who have a knowledge of sanitary engineering, vital statistics and preventive medicine must spend not less than one year on a special subject, and present an acceptable thesis containing results of original research in order to gain the degree of Dr.P.H. Each candidate must, in addition, make a sanitary survey of a city. While one year in residence is the minimum requisite, it is impossible without special experience and qualifications to accomplish all of the requirements in this short time.

While candidates for the degree of Dr.P.H. are advised first to take the medical course, the medical degree is not a prerequisite. Those who desire to specialize in sanitary engineering, sanitary architecture, sanitary biology, sanitary chemistry, demography or some other branch of public health work may receive the degree after no less than four years of graduate work in approved subjects, including an acceptable thesis embodying the results of original research.

The degree of Dr.P.H. does not rest on any computation of time, or on any enumeration of courses; although a student cannot become a candidate until he has, in the judgment of the committee on the degree, fulfilled the requirements of residence and study. The degree is not given for the mere reason of faithful study for a prescribed time or for fulfillment of a determinate program, and never for miscellaneous studies; but only on the ground of long study and high attainment in the special branch of learning manifested not only by examination, but especially by the thesis.

The oral examination consists of a searching inquiry in the fields related to the subject of the candidate's thesis, and furthermore, includes the following subjects: communicable diseases, immunity, heredity, demography, sanitary engineering, sanitary law, hygiene, sanitation and preventive medicine.

The following list of titles illustrates the nature of the work of the candidates for the degree Dr.P.H. at Harvard University:

E. B. Beasley, A.B., M.D., Dr.P.H.: An Investigation on the Permeability of Slow Sand Filters to Bacillus Typhosus, *Jour. Med. Research*, 1911, xxv, 101.

A. I. Kendall, S.B., Ph.D., Dr.P.H.: Certain Fundamental Principles Relating to the Activity of Bacteria in the Intestinal Tract: Their Relation to Therapeutics, *Jour. Med. Research*, 1911, xxv, 117.

E. H. Schorer, B.S., M.D., Dr.P.H.: Experimental Studies on Milk, *Jour. Infect. Dis.*, 1912, xi, 295.

H. L. Amoss, S.M., M.D., Dr.P.H.: Organic Matter in the Expired Breath, with Special Reference to Its Inhibiting Power on Oxidizing Ferments, *Jour. Exper. Med.*, 1913, xviii, 132.

SPLENECTOMY IN PRIMARY PERNICIOUS ANEMIA

W. W. ROBLEE, M.D.
RIVERSIDE, CAL.

Since Addison called the attention of the medical profession to the symptom complex called by him "idiopathic anemia," there has been an immense amount of study devoted to it. In spite of this, until very recently, it has continued to be one of the most hopeless conditions with which we have been called on to cope. Since the middle of 1913, occasional case reports and some lengthy articles have appeared in current medical literature concerning the treatment of this disease by splenectomy. Inasmuch as they have nearly all appeared in German magazines, that this work seems to be of great importance and that up to the present time a careful tabulation of the information on this subject has not been made in The Journal, it appears that the study which follows will be of profit.

The inquiry naturally divides itself into a consideration of:

1. The cause or causes of primary pernicious anemia.
2. The normal function of the spleen.
3. The effects of splenectomy.
4. The clinical results.

CAUSE OF PRIMARY PERNICIOUS ANEMIA

Primary pernicious anemia may be defined as a systemic disease, characterized by a blood picture which shows a high color index, a decrease in number of the erythrocytes, and the constant presence of poikilocytes, megalocytes, nucleated red cells, especially megaloblasts, and polychromatophilic red cells. There is progressive bodily weakness, the lemon-colored skin, digestive disorders, spinal cord symptoms, which may be tabetiform, paralytic or spastic in character, and no pronounced enlargement of the spleen or liver. The etiology is not settled, but the disease must be due to (1) a toxin, which destroys the cells or inhibits their development; (2) a disease of the blood-forming organs, or (3) an increased destruction of the blood cells due to an overaction of the blood-destroying organs.

The Toxin Theory

There is much that leads one to feel that the first or toxin theory is responsible in many cases. Faust and Tallqvist[1] have proved that the anemia caused by the *Bothriocephalus latus* is due to a powerful hemolytic substance, cholesterin oleic acid, which is formed in the proglottis of the parasites. The oleic acid is split up in the stomach; it is combined with alkalies in the intestine, and forms a soap which, when absorbed into the circulation, injures the erythrocytes. K. R. and R. Seyderlein,[2] in some work reported this year on anemia in the horse, have shown that it is due to a substance called by the authors "oestrin," which is elaborated by a parasite, the *Gastrophilus equi*. The anemia may be produced artificially by the injection of a watery extract of these parasites; it is exclusively specific for the horse. It is transmissible from the blood of a diseased horse to a healthy horse, and even the blood of the latter may transmit the disease.

The same arguments apply to hookworm anemia. This was originally supposed to be due to small hemorrhages occurring in the intestines, where they had been injured by the worm, but recently the toxin theory of this disease has been advanced. This is explained as being caused (*a*) by a toxin secreted by the worm, or (*b*) by a toxin produced by intestinal bacteria whose absorption occurs through the damaged epithelium (Nicoll[3]).

Both oleic acid and the "oestrin" of Seyderlein belong to the group of unsaturated fatty acids, and this suggested the thought to J. H. King,[4] who was working in the Eppinger clinic, that the human organism in disease may produce hemolyzing unsaturated fatty acids and if so, the question whether the elaboration of these acids can be ascribed to any of the organs of the body. He directed his study toward the spleen as being the organ thus responsible.

Joannovics and Pick[5] had already ascertained that in chronic toluylendiamin poisoning a great excess of oleic acid was formed, and that after splenectomy in dogs,[6] there resulted a marked diminution in the building of these higher unsaturated fatty acids. They found the same condition to obtain in phosphorus poisoning.

King undertook a series of experiments on dogs in which the quantity of unsaturated fatty acids circulating in the blood was estimated by ascertaining their iodin combining powers, the cholesterins first having been separated from the total lipoids. He found in splenectomized animals an increase of total fats and cholesterins, but a great decrease in the unsaturated fatty acids as expressed by the iodin number. He carried out the same study in three cases of pernicious anemia in man, which came to operation and duplicated the results found in dogs. These findings are of great importance from a therapeutic point of view, as the ordinary fats and cholesterins are protective against hemolytic agents, while the unsaturated fatty acids are decidedly hemolytic in action, splenectomy being thus helpful in two distinct directions. He concludes as follows:

> In pernicious anemia, hemolytic jaundice, some types of catarrhal jaundice, and cirrhosis of the liver, the hyperactive spleen unfavorably influences the anemia through its regulation of the highly hemolytic, unsaturated fatty acids in the blood. Its removal, therefore, appears to be indicated. Splenectomy of itself, besides influencing the production of hemolytic unsaturated fatty acids, raises the percentage of antihemolytic substances in the blood, that is, the total fats and cholesterins.

It has been suggested, after consideration of the hemolytic effects of the poisons of intestinal parasites, that possibly other hemolytic anemias in man may be caused by chemical compounds which are formed in or reach the blood current via the alimentary tract. The amins, for instance, are known to be products of bacterial changes occurring in proteins under conditions which may obtain in the gastro-intestinal tract.[7] Of these compounds, tyramin is especially conspicuous. It has been isolated from putrid meat, cheese and ergot. Oxyphenylethylamin is produced from the amino-acid tyrosin by various races of bacteria, among them the *Bacillus coli communis*, a known inhabitant of the intestinal tract of man. Iwao of Japan produced in animals a severe anemia of the pernicious type by the injection of small doses of tyramin. No studies have yet been made to ascertain what effect splenectomy may have in controlling the effects of poisoning by this group, or of the poisoning occurring from those elaborated by intestinal parasites.

Is Pernicious Anemia Due to a Disease of the Blood-Forming Organs?

In the embryonal life of man, the spleen produces erythrocytes, but this production ceases at birth. The only source from which red cells are produced, in postnatal life, is the marrow of the long bones. Throughout life, a nice balance is kept between production and destruction, so that the normal number of 5,000,000 red cells per cubic millimeter of blood is constant unless interfered with by pathologic processes. The factors in maintaining this balance are unknown, except that the marrow reacts to various chemical and infective agents. It has been suggested that the spleen acts normally to some extent as an inhibitor of the bone marrow, sending forth some influence that keeps a check on red cell production. In pernicious anemia, there is usually found a hyperplasia of the bone marrow. This and the relative abundance of nucleated red cells seem to indicate that the blood-producing organs are regenerating cells at an increased rate. This, however, does not proceed at a rate to compensate for the destruction which is going on. It does not seem probable, therefore, that this is a disease of the blood-forming organs.

Is Pernicious Anemia Due to an Overaction of the Blood-Destroying Organs?

The duration of the life of a red cell is not definitely known under all circumstances, but it probably averages from two to three weeks. There can be no question that the spleen is the organ primarily responsible for the destruction of the worn-out red blood cells. These worn-out cells give up their hematin to the spleen liver circulation. Bilirubin and biliverdin are formed. These are excreted via the bile to the intestines, in which bacterial action reduces them to urobilin in the urine and feces. Eppinger has devised a colorimetric method for this determination, and has laid great stress on the importance of this estimation in all diseases causing hemolysis. In fact, Eppinger and Ranzi state that they consider that enormous amounts of urobilin in the stool, rather than the icterus or spleen tumor, are the chief criterion to guide them in recommending splenectomy in hemolytic jaundice and associated conditions.

[6] Joannovics and Pick: Berl. klin. Wchnschr., 1910, xx.

[7] This is summarized in Experimental Pernicious Anemia and Alimentary Intoxication, editorial, The Journal A. M. A., June 13, 1914, p. 1894.

It seems to be quite probable that some hemolytic substances cause red cell destruction through an increase of splenic activity. It is possible that, as we become more familiar with the spleen and its function, we may find that it, like other ductless glands, the thyroids, adrenals and pituitary, may develop conditions of either hyperexcitability or hypo-excitability and that certain symptom complexes, such as Banti's disease, chronic family jaundice, Gaucher's disease and pernicious anemia, may be properly termed "hypersplenism" and others, polycythemia for example, "hyposplenism."

Just what happens if a condition of hypersplenism exists cannot as yet be definitely determined; whether it always results in an increased production of unsaturated fatty acids with consequent disintegration of the red cells, as the work of King seems to indicate, or whether there may be an increased cellular activity in the spleen itself, or if in some cases there may be a hemolytic effect from intestinal-formed toxins circulating in the general blood stream, or even some factor yet unthought of may be present, cannot now be stated. It is possible that no one pathologic condition is responsible for all cases.

As Moffitt[8] concisely says:

> I think we must, with Waitkin, realize that the infective agent or toxin of pernicious anemia may act differently at different times or that there may be splenic, lymphatic, hemolymphatic or marrow hemolysis. The shifting clinical pictures, the various reactions at different times to remedial measures like arsenic, blood transfusion, thorium X, salvarsan, splenectomy, the marked hemolysis in some cases, and its absence in others, the inconstancy of marrow reaction, all speak for a widespread influence of the poison in the economy with maximum effects apparent now in this organ, now in that.

Eppinger, in studying spleens removed for this disease, has emphasized the fact that the walls of the follicular arteries are thickened, thus causing a narrowing of their lumen, and that for this reason, the blood stream is turned directly into the interstices of the pulp. In one of the two cases in which I operated, the pulp seemed to be hyperemic, but there did not appear to be any marked increase of pigment in the splenic tissue. The other case showed little deviation from the normal. Moffitt reports having studied sections from eight cases in which operation was performed. He reports marked hyperemia of the pulp, little change in capsule or trabeculae, and variable conditions in the follicles. Eppinger feels that the change in the direction of the blood stream results in an increased phagocytic function of the organ.

We may summarize our present knowledge of the cause of primary pernicious anemia as follows: It is probably not due to a disease of the blood-forming tissue, namely, the red bone marrow. It probably is due to a toxin or toxins. This is undoubtedly the case in certain parasitic diseases, and it is probably true that bacterial action in the intestinal tract is responsible in some cases. King's work would indicate that an increase of the unsaturated fatty acids in the blood is present in many cases, and that they are hemolytic in action. The spleen appears to have a direct action in stimulating their production. It is probable also that in other cases there is a condition of hypersplenism with resultant (*a*) overproduction of an unidentified hemolytic substance, or (*b*) an increased cellular activity with resultant red cell destruction beyond the normal in the spleen itself, *because of the change in the direction of the blood stream spoken of by Eppinger.* Because of these considerations, splenectomy as a therapeutic measure was resorted to first about a year and a half ago in the Eppinger clinic, and it was very strongly advocated by Ranzi, who has done much of the operating for Eppinger, in an address delivered before various surgical societies during a trip made by him to the United States in April and May, 1914.

Granted that the spleen has an influence on the production of this disease, the query comes "Do we interfere with any other function of this organ which may be necessary for the well-being of our patients, if removal is resorted to?"

NORMAL FUNCTION OF THE SPLEEN

So far as we know, the functions of the spleen are as follows:

1. It retains the iron set free by destruction of blood cells, whereas the liver stores iron derived from food. These reserves are drawn on for the production of new hemoglobin.
2. It may have some effect on digestion. An improvement in appetite and stomach symptoms is usually noted after splenectomy in blood diseases.
3. The spleen usually enlarges and becomes hyperemic during the course of many infectious diseases. The well-known ague cake is an example. It has been thought that it might act as a protecting organ in systemic bacterial infections. Such a function has not been proved. Patients who have been splenectomized have passed through the various infectious diseases without special difficulty.
4. Experiments on chicken embryos indicate that the spleen exercises an inhibiting effect on the growth of neoplasms.
5. It may regulate the production of erythrocytes.
6. It most certainly destroys those that have reached the end of their usefulness.

We know that when other ductless glands are removed in their entirety, disaster overtakes that individual very speedily. Resection of a *portion* of the spleen is a very difficult piece of work, because of the great vascularity of this organ. The slightest tear in the capsule causes a very free flow of blood, and a temporary compression of the pedicle is dangerous on account of the friability of these tissues.

Mayo[9] has suggested that it may be possible by ligation of one or more branches of the splenic artery at the hilum so to reduce the blood supply as to cause atrophy of the spleen after the manner in which this result is secured in cases of hyperthyroidism.

---

[9] Mayo, William J.: Principles Underlying Surgery of the Spleen, The Journal A. M. A., Jan. 1, 1910, p. 14.

Dr. A. K. Steele, discussing Harris and Hertzog's paper, stated that of six patients operated on, four died, which would give this procedure a much higher mortality than splenectomy. Fortunately, a removal of the spleen does not cause disaster to the economy, and a splenectomy, while a serious operation, is perfectly feasible even in very ill persons, and it is not followed by serious after-effects.

This is probably explained by the fact that there are other organs which are able to compensate for the removed spleen. These are the accessory spleens, hemolymph glands and the thymus. True accessory spleens have frequently been described. The hemolymph glands are found in the thoracic and abdominal aggregations of lymphatic structures. Histologically, in addition to ordinary lymph follicles, there are found lymph sinuses and blood vessels, some of these sinuses being filled with red corpuscles. Cabot declares that in these sinuses the destruction of red corpuscles is considerable.

A number of investigators, notably Waitkin, have found that in dogs after splenectomy there is not only a great increase in size of the hemolymph glands, but also an increase in number. Pearce and Austin[10] found an increase of endothelial cells in the hemolymph glands of dogs following splenectomy, these cells being proved to have a phagocytic power over red cells after the injection of a hemolytic serum.

The thymus has been found to enlarge after splenectomy, and Boyer[11] regards the spleen and thymus as capable of functionally compensating each other. The presence and action of these accessory organs undoubtedly afford an explanation of the facts, first, that the spleen can be, and many times has been, removed without interfering with the well-being of the person operated on, and second, the gradual return of a patient suffering from pernicious anemia, who has been splenectomized, to a final hopeless condition after a marked improvement, immediately following the operative procedure. This was observed in one of my cases.

If we grant that splenectomy is indicated in the group of blood diseases whose presenting symptom is an anemia of the pernicious type, namely, primary pernicious anemia, Banti's disease, splenomegaly of the Gaucher type, chronic family jaundice and possibly Hanot's cirrhosis, it is proper to inquire as to the mortality of this operation. It is a serious piece of work, but the mortality is not high. Rodman and Willard give the mortality from operation in the first and second stages of Banti's disease at 12.5 per cent. The Mayo Clinic reported twenty-five splenectomies for all causes with two operative deaths. Griffin reports three operative deaths in eighteen cases for splenic anemia. Behling reports 8 per cent. mortality in seventy cases. Carsten reports a mortality of 18.5 per cent. in a collection of 739 cases of splenectomy for various lesions.

These figures show that the operative mortality is about that for abdominal neoplasms, the skill of the operator being the great factor for safety in this work. The first operation for primary pernicious anemia was done at Eppinger's request in March, 1913. I have found record of forty cases in which operation has been performed up to the present time; nine patients died either at operation or shortly thereafter. When one considers the desperate condition that some of these patients were in at the time of operation, this is not a high mortality. Both of the patients on whom I have operated had been confined to their beds for several weeks expecting death at any time. In this connection, it is well to bear in mind one very important advance in the therapy of this disease. Blood transfusion should be resorted to in all these cases prior to operation. It does not have a permanent curative effect, but it will bring up the blood count and tone of a patient so that the operative procedure can be carried out with much greater safety. This is a very practical procedure when a good clinical laboratory is at hand, since the method of using defibrinated blood has been perfected, and a classification of donor and recipient can be made after the method of Moss.

EFFECTS OF SPLENECTOMY AND CLINICAL RESULTS

Now the great question comes, "Is splenectomy worth while in primary pernicious anemia?"

What have been the clinical results? So far I have been unable to find a record of any cases that the surgeon has been willing to report as cured. There has been almost invariably an immediate and striking improvement in the blood picture. There is a rapid rise in number of erythrocytes and hemoglobin content, many nucleated red cells appear, and the Howell-Jolly bodies are found in abundance. Cells of the megalocyte type usually persist, and the blood does not resume an entirely normal appearance. The stomach symptoms are improved, and there is a decided gain in strength and spirits. A great sensitiveness of the long bones was present in one of my cases. This has been spoken of in other case reports and doubtless indicates a hyperemia of the bone marrow. Eppinger, Florcken and Mosse report cases in which the patients were clinically well after from six to nine months. Türk[12] gives the best summary of the question I have seen. He says:

> With pernicious anemia, splenectomy induces a marked change for the better, but the blood does not return to the normal type; the patients are much improved, but in none of the seven cases in which splenectomy has been done for pernicious anemia during the last ten months, has the blood picture returned to normal. But a remarkably rapid and thorough-going remission may almost be counted on in apparently moribund patients; it acts more rapidly than arsenic and as promptly as thorium, but it does not seem to remove the cause of pernicious anemia. The morbid spleen functioning is merely one link in the chain of factors causing the disease, but by removing it we make a gap in the chain, and even this is great gain.

There is one variety of this disease that should not be subjected to operation, namely, the anemia of the pernicious type developing in pregnancy. In these cases, which are quite rare, there is usually recovery after the pregnancy has been terminated. This subject is summarized by Schupbach.[13]

Emphasis must be placed on diagnosis in considering operative interference in these cases. No patient should be operated on until a negative Wassermann has been obtained; malaria and the anemias due to intestinal parasites must be excluded. Carcinoma of the stomach frequently gives an anemia of this clinical type, and even after careful clinical search has been made, the first thing to be done after the abdomen has been opened is to make a thorough exploration of the abdominal viscera, and especially of the stomach, for neoplasms. For the sake of accuracy in our statistics, as well as scientific pride, cases of Banti's disease, Gaucher's disease, Hanot's cirrhosis, family jaundice and pernicious anemia should be carefully segregated and thus tabulated.

[12] Türk: Deutsch. med. Wchnschr., 1914, xl, No. 8.

[13] Schupbach: Cor.-Bl. f. schweiz. Aerzte, xliii, No. 47.

I operated in two cases of pernicious anemia in May, 1914. One of these was seen by Dr. Ranzi, who gave me courage to attack surgically what appeared to be a hopeless condition.[14] My experience coincides with others in that there was a marvelous initial improvement which had persisted in Case 2 up to October, 1914. I am sorry to say that I have now lost track of the patient. The other patient began to fail in September. He slowly returned to his bedridden condition. He developed a transverse myelitis, the blood gradually deteriorated, and he died, Dec. 16, 1914, seven months after the splenectomy was performed.

SUMMARY

1. Primary pernicious anemia is probably due to a toxin which may be of bacterial, chemical or parasitic origin, and in some cases there is an increase of the unsaturated fatty acids. The spleen seems to exercise an influence favorable to the elaboration of these substances. These toxins appear also to cause a hyperemia of the splenic pulp because of changes in the blood vessels, which cause the blood to be poured directly into the pulp. The presence of the spleen seems to cause a diminution in the amount of the total fats and cholesterins of the blood which are antihemolytic. For these theoretical reasons, and because of the numerous cases on record in which a cure has been obtained in Banti's disease, which is closely related to pernicious anemia, splenectomy appears to be indicated in these and the closely associated anemias.

2. Removal of the spleen either in sickness or in health does not affect the patient injuriously. The operative mortality is not high even in very weak patients.

3. A rapid and striking remission of all symptoms appears, the change in the blood picture coming quickly and quite certainly. It is too soon for us to know whether or not any patients will be permanently cured, but it is quite probable that a large percentage will succumb to the disease within a few months after operation. Other methods of treatment should be combined with splenectomy, as more than one factor is doubtless at work in these cases. It will certainly prolong life, and in our incomplete knowledge of the etiology of this disease and the certainty that death will come under every other known method of treatment, I believe that these patients should be offered this additional chance of recovery. We must remember that some patients have been reported symptomatically well at the end of nine months, even though the blood was not entirely normal.

---

[14] The early results of these operations I reported in Surgery, Gynecology and Obstetrics, November, 1914.

COMPLEMENT FIXATION IN PARASITIC SKIN DISEASES *

JOHN A. KOLMER, M.D.
Instructor of Experimental Pathology, University of Pennsylvania, School of Medicine; Professor of Pathology and Pathologist to Department of Dermatological Research, Philadelphia Polyclinic

AND

ALBERT STRICKLER, M.D.
Instructor of Dermatology, Philadelphia Polyclinic; Assistant Dermatologist, Philadelphia General Hospital

PHILADELPHIA

In a fairly minute examination of the literature on fungus diseases of the skin, we have found no reference to complement-fixation tests having been made.

This study was undertaken by us in conjunction with investigations on the subject of vaccine treatment of ringworm and favus, to determine if various pathogenic fungi stimulate the production of amboceptors, as possibly shedding more light on the mechanism of the immune processes operative in these infections.

We have found that, in the majority of cases of ringworm of the scalp and favus, complement fixation occurs with fungus antigens, and while this test may have a limited practical value, owing to the ease with which the diagnosis of these diseases may be made from the clinical aspects, supplemented by a microscopic examination of diseased hairs, in the diagnosis of doubtful cases the complement-fixation test may prove of value.

Since ringworm of the scalp is to be regarded as a superficial invasion of the tissues of the scalp, the invasion of the fungus usually being limited to the shafts of hairs and the neighboring cells of hair follicles, it is of added interest that antibodies, which may be demonstrated in the serum of a person with this disease by the complement-fixation technic, may be produced by mere parasitic invasion without true infection, if the latter term is restricted to a process characterized by the passage of a microparasite through the barrier epithelium to the tissues beneath. It is conceivable that the fungus of ringworm may produce soluble products which, being absorbed, are capable of stimulating the local and general body cells to produce antibodies.

Favus, on the other hand, is usually characterized by a well-marked invasion of all layers of the epiderm down to and not infrequently involving the underlying corium, so that in most instances the disease may be regarded as an infection in the true sense of the term.

Of interest in this connection is the demonstration by Plato, Truffi, Black and Massini of local and general allergic reactions in persons suffering with ringworm by the application or injection of "trichophytin," an extract prepared of cultures of the fungus indicating the presence of a lytic antibody in the body fluids of persons suffering with this disease.

Further interest in this subject refers to the possible interrelationship of the fungi of ringworm and favus as studied by a complement-fixation technic. Bodin has described cases in which lesions on the skin, similar to those produced by the trichophyton of ringworm, have been caused by a parasite of the nature of an achorion. Fox, Blaxall and Sabouraud have

---

* From the Laboratories of the Philadelphia Polyclinic and College for Graduates in Medicine.

observed circinate lesions on the skin, and lesions like kerion on the scalp, similar to those produced by the trichophyta, which, on cultivation, gave a culture like that of favus. Such cases demonstrate the fact that the line of demarcation between the fungi of ringworm and favus is not well defined.

MATERIALS

Serums.—The serums of twenty-seven cases of ringworm of the scalp were studied; also the serums of three cases of favus and one of tinea versicolor. Most of these patients were in the services of Dr. Jay F. Schamberg in the Polyclinic and Philadelphia General hospitals.

In addition, the serum of rabbits immunized with repeated intravenous injections of the antigens of ringworm and favus fungi were employed in the study of the biologic relationship of these fungi.

Cultures.—Pure cultures of the ringworm and favus fungi were obtained by culturing diseased hairs in "French proof agar." In obtaining these cultures, diseased hairs were placed in a shallow dish of absolute alcohol for fifteen or twenty minutes, washed in sterile salt solution and planted at once on a layer of the medium contained in 250 c.c. wide-mouthed Erlenmeyer flasks. These were placed at room temperature for twenty-four days, and the colony studied. Usually the fungi could be obtained in pure culture, fulfilling the cultural and microscopic appearances of *Microsporon audouini* and the achorion of Schönlein, respectively.

For cultivating the fungus of ringworm, a maltose medium was employed:

Maltose	38 gm.
Agar-agar	13 gm.
Peptone	5 gm.
Distilled water	1,000 c.c.

For the achorion of Schönlein (favus) the following medium of Sabouraud was successfully employed:

Pure anhydrous glucose	40 gm.
Peptone	20 gm.
Agar-agar	15 gm.
Distilled water	1,000 c.c.

While cultures were not made of all our cases of ringworm, all of those obtained were identified as the *Microsporon audouini*.

While many attempts have been made to cultivate *Microsporon furfur,* the fungus of tinea versicolor, these have generally failed. One of us has succeeded in cultivating a fungus from the scales of epithelium from a patient with this disease which we regard as a doubtful culture of the fungus. It was used in this study in our endeavor to throw more light on its identity.

Antigens.—These were prepared as follows:

Twenty-four day cultures were carefully removed from the flasks of medium with due caution against tearing away portions of the medium. As the cultures are firmly adherent, this is difficult and practically impossible to avoid entirely. An entire colony was placed in a sterile mortar, and 4.25 gm. of crystals of pure sodium chlorid added. By prolonged trituration the mycelia were broken up and the homogeneous material obtained. To this were added 500 c.c. of sterile distilled water. The resulting emulsion was then isotonic, and after being shaken mechanically with glass beads, was heated at 60 C. (140 F.) for an hour, preserved with 0.25 per cent. phenol (carbolic acid) and used as antigen. Large flakes from the emulsion will settle to the bottom of the flask, and these may be discarded after pipetting off the supernatant emulsion. Under no circumstances, however, may the emulsion be filtered through paper or porcelain, as these hold back the particles of mycelia, yielding a filtrate poor in antigenic properties. The ringworm antigen employed was prepared of three different cultures of *Microsporon audouini.*

TECHNIC

A. *Hemolytic System.*—The antisheep hemolytic system was used throughout in the same amounts as in our Wassermann technic, namely, one-half the amounts used in the original Wassermann method. Washed sheep's corpuscles were made up in a 2.5 per cent. suspension and used in doses of 1 c.c.; the fresh serums of guinea-pigs were diluted 1:20 and used as complement in dose of 1 c.c.; the hemolysin was titrated each day, and two hemolytic units used.

All serums were heated to 55 C. (131 F.) for one-half hour and used in amounts of from 0.001 to 0.2 c.c. Serum, antigen and complement were incubated for one hour at 37 C. (98.6 F.), and hemolysin and corpuscles added, incubated for an hour or longer, depending on the hemolysis of the controls, and the readings made.

By titration of the hemolysin with each complement and corpuscle suspension to be used that day, the hemolytic system is accurately adjusted. The controls were the same as we used in the routine Wassermann reaction; a serum control with each serum in maximum dosage; antigen, complement, hemolytic and corpuscle controls.

B. *Antigen Titrations.* — The anticomplementary dose of each antigen was determined by titration at frequent intervals, and one-quarter the anticomplementary dose used as our antigenic dose. With these amounts, false reactions were avoided. The antigens were always preserved in a refrigerator, and their titer remained remarkably constant over periods of several months.

Table 1 shows the results of one set of these titrations preliminary to the tests proper.

TABLE 1.—ANTICOMPLEMENTARY TITRATION OF ANTIGEN*

Dose of Antigen,† c.c.	Microsporon Audouini	Achorion Schönleinii	Microsporon Furfur (?)
0.2	H.	H.	H.
0.4	H.	H.	H.
0.6	H.	H.	H.

1.5	M. I. H.	I. H.	H.
2.0	I. H.	I. H.	S. I. H.

* In this table, I. H. = Complete inhibition of hemolysis; M. I. H. = Marked inhibition of hemolysis; S. I. H. = Slight inhibition of hemolysis; H = Complete hemolysis.

† Antigenic dose used: Microsporon audouini, 0.3 c.c.; Achorion schonleinii, 0.25 c.c.; Microsporon furfur, 0.5 c.c.

I. COMPLEMENT FIXATION IN RINGWORM OF THE SCALP

With the serums of twenty-three cases of tinea tonsurans, positive reactions were obtained with the polyvalent antigen of *Microsporon audouini* in eighteen, or 78 per cent. Not all of these cases were cultured to determine whether the fungus was the *Microsporon audouini* or the *Trichophyta endothrix* or *ectothrix.*

Table 2 gives the results of complement-fixation tests with a constant dose of the antigen and increasing doses of serum. The age of the patient, and the duration and extent of the disease are included.

As shown in this table, we observed complement fixation with the majority of serums tested, especially with the 0.2 c.c. dose of serum. In general, the degree of complement fixation bears some relation to the severity and duration of the infection. One case of two weeks' duration, the earliest one among our cases, yielded slight fixation with the maximum dose of serum, but the duration of the disease appears to have less relation to the degree of fixation than the severity of the infection.

TABLE 2.—COMPLEMENT FIXATION IN RINGWORM OF THE SCALP*

No.	Name	Age, Yrs.	Probable Duration, Mos.	Extent of the Disease	Reactions				Serum Control

† Months.

II. COMPLEMENT FIXATION IN FAVUS

Owing to the comparative rarity of this disease in this country, we have had the opportunity of studying but three cases. One of these was tested with the antigen of ringworm alone and the two recorded in Table 3 with the favus antigen.

TABLE 3.—COMPLEMENT FIXATION IN FAVUS

No.	Name	Age, Yrs.	Probable Duration, Yrs.	Extent	Reactions				Serum Controls, 0.2 c.c.
					0.01 c.c. Serum	0.05 c.c. Serum	0.1 c.c. Serum	0.2 c.c. Serum	
24	Z.	..	..	Moderate	—	+	++	+++	—
25	R.	10	7	Moderate	+	++	++++	++++	—

In both cases, positive reaction of well-marked degree were observed.

III. BIOLOGIC RELATIONSHIP OF MICROSPORON AUDOUINI AND ACHORION SCHÖNLEINII

The determination of the biologic relationship by complement-fixation tests of a microparasite to others of a group bearing similar morphologic or cultural characteristics depends on whether or not the organism produces a specific amboceptor and the antigen in the test possesses the distinct antigenic principle.

We have studied these relationships by two main methods: (*a*) by testing many serums of ringworm, favus and tinea versicolor infections with all three antigens, and (*b*) by interaction of the immune serums of ringworm and favus with the respective antigens.

TABLE 4.—INTERCOMPLEMENT-FIXATION REACTIONS WITH PATIENT'S SERUM

		F. versicolor?	—	—	—	—

Table 5 shows the results of testing a number of serums in the maximum dosage of 0.2 c.c. with each of three antigens.

TABLE 5.—INTERCOMPLEMENT-FIXATION REACTIONS WITH PATIENTS' SERUMS (Continued)

Case No.	Disease	Dose of Serum, c.c.	Antigens			Serum Control 0.2 c.c.
			Ringworm	Favus	T. versicolor?	
16	Ringworm	0.2	++++	++++	—	—
7	Ringworm	0.2	++++	++++	++	—
19	Ringworm	0.2	—	—	—	—
4	Ringworm	0.2	++	++	±	—
20	Ringworm	0.2	+	+	±	—
3	Ringworm	0.2	+	±	—	—
2	Ringworm	0.2	+	—	—	—
1	Ringworm	0.2	++++	++++	+++	—

The results may be summarized as follows:

1. With the serums of patients suffering with ringworm, complement fixation was best marked with ringworm antigen; usually to a lesser degree with favus antigen and not at all or but a slight degree with the antigen of a doubtful culture of tinea versicolor.

2. The serums of persons suffering with favus fixed complement best with the antigen of the favus fungus, to a lesser degree with the antigen of ringworm, and in one case somewhat strongly with the antigen of doubtful culture of tinea versicolor.

3. The serum of the one case of tinea versicolor failed to fix complement with any of the three antigens.

4. These reactions tend to show that a close biologic relationship exists between *Microsporon audouini* and *Achorion schönleinii*. For the purposes of differential diagnosis, therefore, it is necessary to use the serum in ascending doses with a constant dose of each antigen (as one-quarter the anticomplementary unit). Specificity is found only with the smaller doses which show fixation of complement with the respective antigen, whereas with the larger doses of serum, complement is absorbed with both antigens in a group reaction.

This relationship is further shown in the results of titrating each immune serum (prepared by immunizing rabbits) with all three antigens (Tables 6 and 7). Each immune serum fixed complement best with its own antigen, which was especially observed with the smaller doses of serum. With the larger doses this specificity was lost and the results constituted an example of a "group reaction" as seen in similar studies with the group of streptococci, diphtheria bacilli, typhoid colon group of bacilli and the gonococcus group. Granting that our antigens were of true cultures of *Microsporon audouini* and the achorion of Schönlein, respectively, the results indicate that these fungi are related and members of the same group.

IV. SPECIFICITY OF COMPLEMENT FIXATION IN RINGWORM AND FAVUS

Most interest in this connection refers to the possibility of the serums of syphilitic persons reacting with the fungus antigens. We have tested a number of the serums from persons with various diseases, including syphilis, and have found that they have in no instance reacted positively with the fungus antigens.

Each serum was also tested by the Wassermann reaction, three different extracts, as follows, being used: a cholesterinized extract of human heart, an alcoholic extract of syphilitic liver, and an extract of acetone-insoluble lipoids of beef heart.

The results are given in Table 8.

These results may be summarized as follows:

1. Eleven serums yielding positive Wassermann reactions reacted negatively in each instance with the antigens of the three fungi. These results indicate quite clearly that the lipophilic reagin in the blood serum of syphilitics responsible for the Wassermann reaction will not absorb complement with the fungi antigens.

2. With the serums of persons suffering with various other diseases, including four skin diseases, namely, scabies, impetigo contagiosa, eczema and acne vulgaris, the reactions with the antigens of fungi were entirely negative.

3. These results indicate that while the reactions are not highly specific with the two fungus diseases, namely, ringworm of the scalp and favus, owing probably to a biologic relationship of these fungi, complement fixation does not occur with these antigens of fungi and the serums of various other diseases.

SUMMARY

1. With a polyvalent antigen of *Microsporon audouini*, complement fixation was found to occur in 78 per cent. of persons suffering with ringworm of the scalp.

2. The serums of two cases of favus studied yielded positive reactions with an antigen of the achorion of Schönlein.

TABLE 8.—COMPLEMENT-FIXATION TESTS WITH FUNGUS ANTIGENS AND THE SERUMS OF PERSONS WITH VARIOUS DISEASES

3. The degree of reaction in both ringworm and favus was observed to depend in general, first, on the severity of the infection, and second, on the duration of the infection.
4. A culture of the scales of tinea versicolor, regarded as a doubtful culture of *Microsporon furfur*, reacted weakly or irregularly with the serums of ringworm and favus patients, and negatively with the serum of a case of tinea versicolor.
5. The ringworm and favus antibodies (amboceptors) fixed complement best with their respective antigens, but with relatively large doses of serum this specificity was not observed, owing probably to a biologic relationship of *Microsporon audouini* and *Achorion schönleinii*.
6. The antigens of the fungi did not fix complement with the serums of syphilitics and that of persons suffering from scabies, impetigo contagiosa, eczema, acne vulgaris and other diseases.

SOME CLINICAL FEATURES OF THE WASSERMANN REACTION

EDWARD L. KEYES, Jr., M.D.
NEW YORK

I. THE WASSERMANN DIAGNOSIS

The Wassermann reaction is the most satisfactory laboratory test for the presence of syphilis. Indeed, some serologists believe this reaction an absolutely accurate test for syphilis. So much one may infer from recent testimony of a competent serologist to the effect that a positive Wassermann reaction, unsupported by clinical evidence, is proof of the existence of syphilis; while a negative Wassermann reaction (in the absence of other evidence) is proof of the absence of syphilis. Such an opinion is of course an extreme one. Most of us agree that the Wassermann reaction when negative gives no information as to the presence or absence of syphilis. Yet many laboratory workers and many clinicians regard the positive Wassermann reaction, unsupported by clinical evidence, as adequate proof of syphilis.

To this opinion I must take exception. I do not feel justified in making the diagnosis of syphilis on the Wassermann reaction alone. To be sure, the positive Wassermann reaction throws the burden of proof on the clinician, and requires that he prove the patient free from syphilis. And most unfortunately, the clinician has no means of proving any one free from syphilis; so that the best he can do in deciding on the merits of any individual case is to leave the question open without asserting that the patient is any more syphilitic for having a positive Wassermann reaction than if he had a negative reaction. Such a conclusion, or lack of conclusion, is obviously a most unsatisfactory one for all concerned. Yet the following facts appear to justify it:

In the first place, the Wassermann reaction is performed in many different ways. All of them give a majority, even a large majority, of accurate results. All of them give a certain small percentage of positives with patients who have no history and present no symptoms of syphilis. But no two of them agree precisely in their results. Some 5 or 10 per cent. of persons apparently free from syphilis give positive Wassermann reactions; but the precise composition of this 5 or 10 per cent. varies with the technic employed.

In order to control possible errors, certain laboratory workers employ two or three different methods (the method varying chiefly in the antigen employed). This, while it increases the accuracy of conclusion, concedes its essential inaccuracy.

In the second place, even in the laboratory itself, the Wassermann reaction with the patient's blood is by no means the only test of syphilis; nor is it always the final test. Its findings vary inexplicably in certain cases from those of the luetin test, as well as from the lymphocyte count, the globulin test and the Wassermann reaction of the spinal fluid. The reaction is positive in practically 100 per cent. of syphilitics at about the tenth or twelfth week of untreated syphilis; but earlier than this, as well as later than this, it is not always positive.

In the third place, the reaction is known to be positive in certain diseases other than syphilis. The striking disagreement among published reports as to the influence of such conditions as tuberculosis, carcinoma and scarlatina on the Wassermann reaction is perhaps the best commentary on the uncertainty of the reaction as a sufficient criterion of the existence of syphilis. We know that with certain technics the percentage of positives in cases of carcinoma and tuberculosis is higher than with others. Indeed, we know that whatever the technic employed the use of alcohol by the patient may render his blood negative; while the presence of acidosis in a person not suffering from syphilis makes his blood positive. This last fact has been demonstrated by Dr. Richards, and is beautifully illustrated by a patient with carcinoma on whom the Wassermann reactions were done by Drs. Coca and L'Esperance. When first examined the blood was found negative; a condition of acidosis was then artificially induced and the blood became positive; finally, when the acidosis disappeared, the blood was again negative. Surely in the presence of these known causes of variation, we must confess that there may be other causes of variation as yet undiscovered. Hence the Wassermann reaction, accurate as it is in the great majority of cases, is by no means in practice, any more than it is in theory, an infallible specific reaction for syphilis.

Only recently, in conjunction with another syphilologist, I examined forty inmates of a tuberculosis hospital on whom the Wassermann reaction had been reported positive. Thirty of these showed certain or probable clinical evidence of the disease; ten of them failed to show any such evidence. The blood of these ten was once again examined. The laboratory which had examined them before (with alcoholic antigen) returned them all once again as positive (three and four plus). Another laboratory employing two different antigens obtained, with a cholesterinized antigen, four positives and six negatives; with a lipoid antigen, one positive, one doubtful and eight negatives.

Under these circumstances I should be unwilling to go on the witness stand and swear that even this last survivor of all the tests has syphilis. Moreover, it is interesting to note that the worker who obtained the ten positives assures me that all of those patients are certain syphilitics; while the man who got the one positive agrees with me that he would not be willing to condemn that one. May I, as a clinician, suggest that the latter attitude seems to me the reasonable one?

The difference in point of view is not due to failure on the part of the laboratory, but to failure on the part of the clinician. The laboratory worker in making up his statistics depends far more on the clinician than the clinician in making his diagnoses depends on the laboratory.

Since 1910, I have depended chiefly on the technic of Drs. Coca and L'Esperance for the Wassermann reaction. During this time they have compared their technic with several others, while the laboratory diagnosis has been controlled by the most careful clinical examination, supported, when necessary, by other laboratory tests.[1] The discrepancy between our conclusions and those of others who have discussed this subject lies, I repeat, rather in the clinic than in the laboratory. The average laboratory worker, human though he be, is far more precise, far more prudent in his conclusions, than the average clinician. If our differences are to be settled, this must be accompanied by the collaboration of skilled clinicians and skilled laboratory workers, studying the comparative accuracy of the various modifications of the Wassermann reaction on a large series of normal individuals as well as syphilitics.

II. THE WASSERMANN REACTION AND PROGNOSIS

The first question asked by every syphilitic is, Can I ever get well? The second, May I ever marry? Since the second question can be answered more definitely than the first, let us give it precedence.

Under the old dispensation, before there was any Wassermann reaction, the syphilitic might safely be told to marry after five years of his disease, during the first three of which he had taken treatment, and during the last two of which he had taken no treatment, and shown no lesions. (Some clinicians insisted on a longer probation, some permitted a shorter one, but we have always adhered to the five years, and it seems a fair average.) It was recognized that this clinical evidence gave no guarantee against relapse in the person of the patient himself; but the matrimonial guarantee was believed sufficient. Indeed, neither I, nor my father before me, have ever known it to fail, though a few exceptions have been alleged by such extremists as Edmond Fournier. But the Wassermann reaction shows no concordance whatever with this opinion. Though it is not positive quite so often after the first five years of the disease as during them, it is far more often viciously and persistently positive in the later years, and patients are often refused permission to marry on account of a positive reaction.

On the ground of infectiousness this is no more warrantable now that we know the Wassermann reaction is positive or negative, than it was when we had no such knowledge. We may believe that a persistent Wassermann proves the presence of the live treponemes in the patient's body; but we also believe that a negative Wassermann is no evidence whatsoever that the treponemes have departed therefrom. Yet clinical experience has long since shown that the lapse of time cures the infectiousness of syphilis (as, indeed, it controls syphilis itself) better than any treatment. Salvarsan and mercury control the outbreaks of the disease. Time and the patient's own reaction abate its tendency to infectiousness and to relapse.

Although the persistence of a positive reaction does not prove syphilis infectious, it is disquieting as a suggestion that the patient is likely to have further relapses, and that these are likely to be in the arterial or the cerebrospinal system. My own experience is not sufficient to justify any absolute conclusions in this matter. I recognize that a fixed positive reaction is singularly common in paresis. Yet in a few cases I have seen a Wassermann reaction remain fixed for many years in the face of the most violent onslaught with injections of salvarsan and mercury, the patient all the while persisting in smiling health despite his disease and despite his treatment.

In two instances I have seen a positive Wassermann become spontaneously negative, although vigorous treatment in the preceding years had failed to make it so. That these isolated cases are not necessarily faulty observations on my part is suggested by the well-known fact that occasionally a patient, on whom the diagnosis of syphilis is first made many years after its inception, has a negative Wassermann reaction, although the reaction was doubtless positive at one time, and although no treatment had been administered. In such an instance the reaction must have become spontaneously negative.

The influence of treatment, notably by salvarsan, on the lesions of syphilis and on the Wassermann reaction usually shows a definite sequence. The somatic lesions yield first, the Wassermann reaction, if it has been positive, either remains positive or becomes negative after the lesions disappear. And further, if a relapse of somatic lesions is about to occur, this is likely to be preceded by the reappearance of a positive Wassermann reaction. This train of events, though by no means inevitable, is sufficiently frequent to be depended on, except in those patients whose Wassermann reaction is negative even when their somatic lesions are active. (These usually, though not always, have a brief positive reaction, provoked within the first twenty-four or forty-eight hours following the injection of salvarsan.)

In the first year of the disease, when the active somatic lesions are almost always accompanied by a positive Wassermann reaction, the effect of salvarsan on the Wassermann reaction is often more prolonged, as well as more immediate, than the effect on the somatic lesions. I have records of no less than seven cases, in the first year of the disease, that showed relapse of somatic lesions, while the Wassermann, which previously had been positive, remained negative. Hence a persistence of the negative Wassermann reaction after salvarsan administration, in the first year of the disease, is no guarantee whatever against relapse, and no justification for discontinuing treatment.

Dependence on the negative Wassermann reaction as evidence of cure has led many observers to report erroneously a reinfection of syphilis shortly after the administration of salvarsan. The usual history of such a case is that salvarsan is administered during the primary stage of the disease, or at the appearance of the secondary lesions. All lesions disappear, the Wassermann reaction becomes negative, a varying number of months elapse, during which the patient is exposed to sundry possibilities of reinfection. Then a new chancre appears, the Wassermann reaction remaining negative. In due time the glands in the groin enlarge, the secondary lesions follow and the Wassermann reaction becomes positive, once again to be controlled by salvarsan. Clinicians reporting these cases do not envisage the possibility that the disease may have been almost, but not quite aborted, and that the apparent relapse is but a reinfection from the treponemes persisting in the chancre that appeared healed. Either interpretation is tenable. But I have twice seen patients who had received salvarsan while still in the primary stage develop delayed macular eruptions after several months had gone by. Once I have seen the chancre itself return after a few months. In one instance, chancre, glands and macular eruption all returned with due precedence some four months after the initial lesion had apparently been destroyed by salvarsan injection. This patient had not been guaranteed cured, and I am moved to believe that he told the truth in denying intervening sexual contact. (Similar observations, be it said, have been recorded by Ravaut.[2])

---

[1] This report will soon be published.

Hence the best we can do for the present is to reserve judgment concerning all alleged reinfections occurring within a few months of an alleged "abortion" of syphilis by salvarsan.

CONCLUSIONS

1. A negative Wassermann is not sufficient evidence of the cure or absence of syphilis.
2. A positive Wassermann, unsupported by clinical evidence, is not sufficient evidence of the presence of syphilis.
3. A positive Wassermann does not prohibit matrimony.
4. A fixed, positive Wassermann in the later years of the disease does not inevitably point to the prospect of grave lesions.
5. A negative Wassermann after salvarsan, in the first year of the disease, does not mean that the patient is cured, or that lesions will not reappear before the reaction again becomes positive.
6. The return of chancre, glands, eruption and positive Wassermann reaction, a few months after control of the disease by salvarsan in its first few weeks, does not prove reinfection.

OROYA FEVER

SECOND REPORT *

RICHARD P. STRONG, M.D.
Professor of Tropical Medicine
E. E. TYZZER, M.D.
Assistant Professor of Pathology
AND
A. W. SELLARDS, M.D.
Associate in Tropical Medicine
BOSTON

In a previous article,[1] we reported on our earlier investigations relating to verruga peruviana and Oroya fever. In the present communication we desire to discuss particularly the distribution and seasonal prevalence and the clinical manifestations of Oroya fever.

DISTRIBUTION AND SEASONAL PREVALENCE

Our investigations relating to Oroya fever and verruga peruviana were made in Lima, in the large hospitals in that city, and in a number of the mountain towns in the interior of Peru, particularly San Mateo, Chosica, Santa Eulalia, San Bartolomé, Surco, Cocochacra and Matucana. Cases of verruga peruviana were found in or in the vicinity of all of these towns, and in these localities cases of malaria were also common. Cases of Oroya fever were studied in which the disease had been contracted in or in the vicinity of San Bartolomé and Matucana.

At the present time our knowledge of the geographical distribution of Oroya fever probably is very incomplete. The disease undoubtedly occurs in many of the deep cleft, narrow valleys situated on the western slope of the Peruvian Andes at altitudes of from 2,500 to 8,000 feet. In these districts, as has been intimated, malaria and verruga peruviana are also very common diseases. Owing to the fact that Oroya fever, or Carrion's disease as it is frequently termed in these localities, evidently has so often been confused with other diseases encountered there, and particularly with verruga peruviana, malaria and paratyphoid fever, our knowledge of its distribution even in these regions must be far from accurate. Moreover, it would not be surprising if cases of Oroya fever were subsequently found to occur in other tropical countries. Since the parasite of the disease is difficult to detect, and its parasitic nature hitherto has not been definitely established, it would not seem strange if the disease has escaped observation in other localities where it exists. Like malaria, the disease appears undoubtedly to have a seasonal prevalence, and this appears to be more marked than in the case of verruga peruviana. Oroya fever seems to be much more prevalent in Peru from January to April, and particularly toward the close of the warm, rainy season. In 1913 more cases were observed, according to the hospital reports in Lima, in January, February and March. In April and May there were no admissions with the diagnosis of this disease at the Dos de Mayo Hospital. Our investigations in Peru were largely carried out during the months of June, July and August, which is the season in which neither Oroya fever nor malaria are particularly prevalent there. However, during these months verruga cases were certainly not uncommon, according to our observations.

Odriozola,[2] in that portion of his estimable monograph which relates to the *fièvre grave de Carrion*, in discussing the localities in which this disease is encountered, describes conditions which seem to suggest that the distribution or rather the prevalence of Oroya fever and of verruga peruviana does not always coincide in regard to time and place, any more than does the distribution of verruga peruviana and malaria.

CLINICAL FEATURES

Clinically the disease is particularly characterized by a fever which may be irregular in its course, and in severe infections by a rapid and pernicious form of anemia which results in extreme prostration and frequently in death. In severe infections the patient may not live longer than three or four weeks from the onset of the symptoms.

Descriptions in the literature regarding the clinical manifestations of this disease are often or, indeed, usually confusing, since almost invariably in these descriptions Oroya fever and verruga peruviana are described as merely different stages of the same disease. In the cases of Oroya fever which have terminated fatally, the patients are said to have died in the first stage of the disease, verruga, before the eruption has appeared on the skin. Those cases of true verruga in which an eruption develops are said to be in the eruptive stage of the disease.

[2] Odriozola: La Maladie de Carrion ou la verruga péruvienne, Paris, 1898, Carré and Naud, editors.

Concomitant infections with Oroya fever and verruga peruviana may occur, just as concomitant infections with verruga and malaria commonly occur, but the diseases in both instances are independent infections. The occurrence of malarial attacks in individuals during the stage of incubation of verruga peruviana has often led to the wrong diagnosis of the febrile or Oroya fever stage of verruga peruviana, and hence to a confusion in relation to the symptomatology and other clinical features of Oroya fever as described in medical literature. Also it seems evident from the published accounts that cases of infection with paratyphoid fever which have developed verruga peruviana have been confounded with or diagnosed under the name of Oroya fever or Carrion's disease. Demonstration of this fact is given by the investigations of several observers. Thus Barton,[3] Biffi and Carbajal,[4] Tamayo and Gastiaburú[5] have isolated paratyphoid bacilli from the blood of supposed cases of Oroya fever or cases of Carrion's disease. Obviously it is possible that some cases of Oroya fever are complicated by a paratyphoid infection. It seems obvious that it is largely on account of these facts that the published clinical descriptions of uncomplicated cases of Oroya fever are meager.

From the study of the literature relating apparently to uncomplicated cases of this disease, and from our own observations on other such cases, the following conclusions have been reached in regard to its clinical features.

It is stated that the incubation period is about twenty days, and our observations are not contrary to this idea. In our opinion, however, this statement has not been conclusively demonstrated, and we were unable definitely to verify it owing to the fact that we did not have an opportunity to observe a sufficiently large number of cases from which to draw definite conclusions. The disease is usually introduced by malaise, pains and weakness in the limbs, and indisposition. Following these symptoms, slight rigors and fever appear. The febrile symptoms and rigors usually increase in severity as the disease develops. The fever is often very irregular, being usually remittent, but sometimes intermittent. The temperature fluctuates between 38 and 38.5 C. (100.4 and 101.3 F.), rarely rising to 40 C. (104.F). The fever is accompanied by a rapid, pernicious anemia, which may be complicated or not by hemorrhage, vertigo or syncope. The number of red cells may be reduced to 1,000,000 per cubic millimeter or less. The skin becomes pale, the mucous membranes assume a waxy appearance, and murmurs are heard over the heart and cervical vessels. Edema of the legs and about the joints may occur. The tongue is coated, and the bowels frequently constipated in the early stages. Later, diarrhea frequently develops. The urine is scanty, and the specific gravity high. Albumin is occasionally present. The prostration increases as the disease progresses, and restlessness, insomnia and delirium may develop. In uncomplicated cases there is no eruption on the skin. It has been assumed by some writers that an eruption in these cases appears in the internal organs. In such an opinion we do not concur, and the results obtained in post-mortem examinations do not coincide with this view. In general, it may be stated that the cases of Oroya fever are grave ones and terminate frequently in death. Mild cases which terminate favorably do, however, occur, and we had an opportunity of studying infections of this nature. In some instances the temperature sinks to normal or subnormal, and death occurs from excessive exhaustion. Death may occur within a few weeks of the onset of symptoms. Some observers report that death may occur as early as ten days from the onset of the attack, but we have not observed instances of such short duration. In the patients who recover, improvement in the severe symptoms of the disease usually begins within twenty-five or thirty days, and convalescence follows. The mortality probably equals usually from 30 to 40 per cent. Some observers, however, give a mortality of 75 per cent., and Rocha-Lima states that it may reach 98 per cent. However, Rocha-Lima's statement is not based on personal observations. The spleen is frequently enlarged, but according to the observations of others is not always palpable. The liver may be moderately swollen, and the lymphatic glands are almost always more or less enlarged. It is stated that pain in the joints is a common symptom, but we are unable to verify this statement in relation to uncomplicated cases of the disease. Pain in the long bones is sometimes complained of.

BLOOD

The most striking and characteristic feature in Oroya fever is the changes found in the blood. This has led to the disease being sometimes termed in Peru *anaemia perniciosa de los quebradas.* The development of the anemia in severe infections may be very rapid and pernicious. In one of the cases studied by us, which was described in a previous report, the red blood corpuscles numbered less than 1,000,000 per cubic millimeter, and the entire course of the disease, terminating in death, was but twenty-eight days. Monge[6] reports cases in which the number of red cells fell to 500,000 per cubic millimeter in a very short period of time, and death followed in a few days. Nucleated red cells appear early in the peripheral circulation, and rapidly increase in number. Normoblasts are most numerous, but megaloblasts are frequently seen. Polychromatophilia and poikilocytosis are particularly marked in severe infections in both erythrocytes and erythroblasts. *Many granular cells* are visible. Great variation in the size of the erythrocytes also occurs. Monge, who has apparently studied uncomplicated cases of Oroya fever, reports in severe ones 2,000 normoblasts and 200 megaloblasts per cubic millimeter. In one case the normoblasts numbered 15,300, and the megaloblasts 3,420. Leukocytosis is almost always present. A count of 20,000 is common. Differential counts often show nothing particularly striking in the proportions of the different varieties. Bassett-Smith[7] found in studying the blood from seven cases that the polymorphonuclears numbered from 65 to 70 per cent., the large mononuclears from 7 to 10 per cent., the small mononuclears from 17 to 21 per cent., transitional forms from 1 to 3 per cent., eosinophils from 2 to 4.5 per cent. Biffi[8] found the polymorphonuclears 44 per cent., eosinophils 10 per cent., large mononuclears 16 per cent., lymphocytes 30 per cent. In the severest case which we encountered, the polymorphonuclear leukocytes numbered 56 per cent., the large mononuclears 16 per cent., transitional forms 0.1 per cent., small mononuclears 12 per cent., eosinophils 0 per cent., normoblasts 9 per cent., myelocytes 2.5 per cent. Myelocytes are found present in the severe cases ranging usually from 0.5 to 2 per cent. The hemoglobin in severe infections may amount to but 15 per cent. In less severe cases of infection it may be from 40 to 50 per cent. In our first publication we gave a description of the parasite as it occurred in the red blood-cells. Other forms of it have subsequently been found in the endothelial cells. To this parasite, which we believe causes the disease, we have given the name of *Bartonella bacilliformis*.[9] In another report which will shortly appear, this organism is fully described, and the description of its life cycle in the endothelial cells considered. In severe cases, the parasites which give rise to the disease are present in the red cells in great numbers. In mild cases, however, the number of infected corpuscles is small and a long search is often necessary to disclose the parasites.

CLINICAL EXPERIENCE WITH LIQUID PARAFFIN (LIQUID PETROLATUM)

A COMPARATIVE INVESTIGATION MADE UNDER THE AUSPICES OF THE COUNCIL ON PHARMACY AND CHEMISTRY [*]

W. A. BASTEDO, M.D.
NEW YORK

During the past three or four years, "mineral oil" has come into extensive use in the treatment of constipation. Preparations of the Russian and the American oil, both heavy and light, have appeared on the market, but there have been no satisfactory data on which to base a selection of oil for use. Therefore, in order to obtain reliable clinical information concerning the relative efficiency of the different oils, the Therapeutic Research Committee of the Council on Pharmacy and Chemistry of the American Medical Association submitted samples of the oils to various clinicians for testing. The following is a synopsis of the investigation, which I have prepared at the request of the committee.

The collaborators were advised that specimens of the best obtainable light Russian liquid petrolatum, heavy Russian liquid petrolatum and an American brand of liquid petrolatum would be sent out, but that, to avoid bias, these specimens would be distinguished only by numbers or letters. The oils sent out were (1) a light "Russian" liquid petrolatum having a specific gravity of 0.860 at 20 C., (2) a heavy "Russian" liquid petrolatum having a specific gravity of 0.885 at 20 C., and (3) an "American" liquid petrolatum having a specific gravity of 0.857 at 20 C. and being markedly fluorescent. The collaborators were advised that the reports should furnish information as to size and frequency of dose, the agreeableness to the taste, the effect on the stomach, the number and character of the stools, the degree of admixture of the oil with the other ingredients of the stool, the degree of leakage of oil about the anus, and the need of other cathartic measures.

Reports have been received from Drs. L. F. Barker, W. A. Bastedo, J. B. Champion, Henry A. Christian with C. K. Drinker and F. A. Hatch, Alfred Stengel and R. L. Wilbur.

CONCLUSIONS

The conclusions to be drawn from the clinical reports are:

Dosage.—Half an ounce to 3 ounces a day. In the same patient, the same amount of each of the oils was required.

Frequency of Dose.—The same amount daily seemed as efficient when given in one dose as when given in divided doses two or three times a day.

Agreeableness to the Taste.—There is a difference of opinion in this regard. Two reports favored the heavy Russian oil. One report favored the light Russian petrolatum. But the taste of any of the samples was so slight as to be a negligible quantity after the patient had taken the remedy for two or three days.

Stomach Effects.—In about 20 per cent. of the patients, the oil produced a slight degree of nausea or tended to repeat. This is most likely in patients who have gastric stagnation with retarded emptying of the stomach. All the oils acted the same in this regard. Vomiting was reported in two cases.

Number of Stools.—To produce one or two copious stools a day the dose required varied considerably, but there was no difference noted on account of difference in the specific gravity or character of the oils.

Character of Stools.—The stools were soft, usually formed, sometimes mushy, obviously greasy. They had a peculiar odor described as sour. Their consistency varied with the dose, but was the same for the different kinds of oil.

Admixture of Oil with Other Ingredients of Stool.—Generally well mixed, but from time to time a patient would have a stool of free oil. This occurred with all varieties of oil. (It necessitated reduction of the dose, and if then the bowels were not active enough, the administration in addition of cascara, aloin, etc.)

Leakage About the Anus.—A disagreeable feature complained of by many is that when they take enough of the oil to move the bowels, there is sufficient leakage from the anus to keep the neighboring skin continually in a greasy condition, and sometimes to stain the clothes. That there is any difference in this regard between the oils has not been determined.

In the reports, one clinician noted no differences that were not negligible. Another was slightly in favor of No. 2 (heavy Russian) as regards taste. A third reporter did not make comparative tests. A fourth is slightly in favor of "B" (heavy Russian) as regards taste and general suitability. All of the findings of this investigation are based on hospital cases. A fifth reporter favored No. 1 (light Russian petrolatum). He considered it the most prompt in its effect, the most uniform in results, and the most prone to give a satisfactory admixture of the oil with the other materials. The difference, however, from the other oils was not marked. Another reporter noted no special differences.

[9] Dr. P. W. Bassett-Smith has since our first publication in THE JOURNAL kindly called the attention of one of us to the fact that the name Bartonia first suggested by us, has been used as a generic one in botany to include two species of Gentianaceæ. This use would not necessarily preclude its employment in zoology, although a duplication of names in botany and zoology is certainly highly undesirable. On investigation, however, we have found that the use of Bartonia as a generic name has been applied by Cossmann (Paris, 1901, p. 293) to an eocene mollusk, *Bartonia canaliculatum*; hence we have changed the generic name to Bartonella, retaining the specific one, bacilliformis (*Bartonella bacilliformis*).

[*] This investigation was made under the auspices of the Committee on Therapeutic Research of the Council on Pharmacy and Chemistry of the American Medical Association. At the request of the committee, Dr. W. A. Bastedo has prepared this critical review of the reports made by those who collaborated in this investigation.

SUMMARY

The results of this clinical investigation appear to warrant the conclusion that so far as therapeutic results are concerned the differences in the action of the three varieties of liquid petrolatum, namely, light Russian liquid petrolatum, heavy Russian liquid petrolatum and American liquid petrolatum, are too slight to be of importance. Hence the choice between the lighter and the heavier oils, and between the Russian and the American is an open one, to be determined not by therapeutic differences, but by palatability, dependent on the degree to which the refinement of the oil is carried out. The U. S. Pharmacopeia, the revision of which is now nearing completion, no doubt will furnish standards which will insure a suitable product. From the findings of the foregoing report it would appear that a satisfactory standard might permit the use of either Russian or American oil, if suitably refined so as to be as nearly as possible devoid of odor and taste.

A STUDY OF THE COMMERCIAL PREPARATIONS OF BACILLUS BULGARICUS

ARTHUR J. BENDICK, M.D.
NEW YORK

During the past few years many physicians have advocated the administration of living cultures of *Bacillus bulgaricus,* in order to change beneficially the intestinal flora. It is asserted that the large amount of acid produced by this organism from the fermentation of the various sugars is detrimental to the growth of other intestinal organisms, especially of the putrefactive group. This organism was at first given in the form of a fermented milk, but is now dispensed chiefly in the form of pure cultures, either in liquid or in tablet form. The potency of these cultures was the object of this investigation.

These cultures are sold either as liquid cultures—broth or whey—or in the dried form as tablets. The majority of the manufacturers simply label their product as living cultures of *Bacillus bulgaricus,* but do not state how many living organisms are present. Some state the number of bacilli present, but add that the count was made by some staining method (Wright), which method does not differentiate between living and dead organisms. As the therapeutic agent is the acid produced by the metabolism of the living organism, any count which does not differentiate between living and dead organisms is of no importance.

The *Bacillus bulgaricus* grows with difficulty on the usual laboratory mediums, but grows readily on mediums containing milk or whey. It ferments glucose and lactose readily, producing a large amount of acid, and the resulting acidity gradually kills the organism. It is this factor of acid production which is one of the principal causes of the rapid deterioration of the liquid preparations.

The names of the preparations tested are not given because not sufficient of each was tested to say which were uniformly bad or good. In the liquid preparations, those giving the highest counts were all obtained direct from local manufacturers from freshly prepared lots. The same preparations bought in the open market in other parts of the country would undoubtedly show much poorer results. In the more complete investigation which is being continued, I hope that results will be more definite, and that I shall be able to publish the names of those manufacturers who control their product so that it is uniformly good, and also to expose those whose preparations are practically inert or heavily contaminated.

In order to make an exact count of the number of living organisms in the preparation, it is necessary to plate them in suitable mediums in varying dilution, and after incubation to count the number of colonies. As the different strains of *Bacillus bulgaricus* vary in their cultural characteristics, each specimen was plated on four different mediums, and the highest count obtained on any one of the four mediums is the count that is listed. Plates were examined after three days' incubation at 40 C. (104 F.). The final count was made after five days' incubation.

The following plating mediums were used.

1. Veal infusion glucose agar.

To the veal infusion were added 2 per cent. agar, 2 per cent. glucose, 0.5 per cent. salt and 2 per cent. peptone, and the medium was titrated to 1 per cent. acid to phenolphthalein.

2. Whey glucose agar.[1]

Whey was obtained by adding glacial acetic acid to hot milk. To this were added 2 per cent. peptone, 2 per cent. agar and 1 per cent. glucose, and titrated to 1 per cent. acid.

3. Whey glucose calcium carbonate agar.[2]

This was the same as the previous medium, with the addition of a few drops of sterile powdered calcium carbonate in water just before plating.

4. Veal infusion whey glucose agar.

This was the same as the first medium, but after cooling to 45 C. (113 F.), one-fourth the volume of warm whey was added. This whey was prepared by rennet coagulation of certified milk. The coagulated milk was heated in the Arnold, and the whey thus obtained was filtered through paper and then sterilized.

Each specimen was also inoculated into the following tube mediums:

1. Litmus milk.
2. Whey.
3. Peptone glucose whey.
4. Veal infusion broth.

These tube inoculations served to control the plating mediums. In no case in which similar organisms were not obtained on one of the plating mediums was a growth obtained in any of the tubes.

The following specimens were tested:

1. Liquid. Obtained direct from manufacturer, freshly prepared lot. Broth culture in small bottles. Not dated.

[2] Bendick: The Use of Calcium Carbonate in Solid Media for the Differentiation of Sugars Fermenting Bacteria, THE JOURNAL A. M. A., Oct. 21, 1911, p. 1343.

Aug. 7, 1914, count showed 5,200,000 organisms per cubic centimeter. August 24, count showed 1,400,000. September 1, count 1,200,000. October 13, 1,200. October 30, specimens were sterile.

2. Liquid. Direct from manufacturer. Freshly prepared. Not dated. Direct plating, August 7, showed 40,000,000 per cubic centimeter, but by September 1, specimens were sterile on three separate examinations.

3. Liquid. Large bottle containing clear fluid with a heavy white precipitate which was readily miscible. Bought from retail druggist, Nov. 24, 1914. Was dated with date of manufacture, Oct. 24, 1914, with statement that it was good six weeks from date. Direct plating showed 5,600,000 per cubic centimeter. No contaminations. Organism grew vigorously and fermented dextrose rapidly. By December 9, the count had fallen to 1,700; December 31, to 124.

4. Liquid. Broth culture in small bottles. Bought from retail druggist, Nov. 24, 1914. Expiration date, Dec. 28, 1914. Immediate plating showed a count of 6 per cubic centimeter. December 7, specimen was sterile on three separate examinations.

5. Liquid. Bought direct from manufacturer, Nov. 26, 1914. Expiration date, June 30, 1915. Broth in small bottles. Direct plating, one bottle gave a count of 12,400 per cubic centimeter, but another bottle gave a count of only 2 per cubic centimeter. Dec. 31, 1914, one bottle gave a count of 95; another was sterile.

6. Liquid. Broth culture in small bottles. Left by demonstrator at physician's office. Expiration date, Jan. 23, 1915. Direct plating, Dec. 1, 1914, showed specimens sterile on three separate examinations.

7. Tablet. Bought from wholesale druggist, Dec. 3, 1914. Expiration date, Feb. 1, 1915. Tablets disintegrated rapidly in water, forming uniform mixture. Direct plating gave a count of 21,600 per tablet. December 15, a count of 10,200 was obtained.

8. Tablet. Bought from retail druggist, Dec. 9, 1914. Expiration date, April 23, 1915. Direct plating gave a count of 120 bacilli in a tablet.

9. Tablet. Bought from wholesale druggist, Dec. 3, 1914. Expiration date, March 1, 1915. Plating showed the tablets to be loaded with contaminations, a count of 59,200 other organisms being obtained. A moderate number of the *Bacillus bulgaricus* were present. Direct examination under the microscope of a tablet crushed in water showed the presence of numerous short motile bacilli, also a few long non-motile bacilli. Milk fermentation was atypical, digestion of the milk occurring with gas fermentation.

10. Tablet. Bought from retail druggist. Not dated. Told would keep indefinitely. Immediate plating showed numerous molds and a few short motile bacilli. On broth a heavy pellicle was obtained, and the milk was digested and gas formation occurred. No bacilli of the bulgaricus type were isolated.

11. Tablet. Bought from wholesale druggist, Oct. 19, 1914. Expiration date, Nov. 28, 1914. Immediate examination gave no growth on the plates, or in the milk, whey or broth.

12. Tablet. Obtained direct from manufacturer. Freshly prepared. One tablet gave a count of 105. Another 62. Three tablets were sterile.

Heineman and Hefferan[1] have demonstrated that *Bacillus bulgaricus* occurs normally in the feces of cows, horses and human beings; also in market milk and in soil. There is consequently no significance in the ingestion of a few bacilli in the commercial preparations. To be effective, the organisms should be present in large numbers. The commercial preparations should therefore be more carefully controlled, especially during transit and storage. I would suggest the following changes:

1. Preparations should be marked with the average number of living organisms to the cubic centimeter as determined by cultural tests, and also what percentage of these will be alive after definite intervals. This method would allow of accurate dosage, and give useful information. A count by the Wright method or a Gram stain is of no significance.

2. Preparations should be marked with the date of manufacture with a statement of how long the preparation is potent. The present custom is to date with an expiration date, which method is a temptation to an unscrupulous dealer, and does not tell the age of the preparation.

3. Preparations should be kept in a suitable ice box as much as possible from the time they leave the manufacturer till they reach the patient. Cultures should therefore be obtained either direct from the manufacturer or from a few well-controlled supply depots.

CONCLUSIONS

1. The majority of the preparations of *Bacillus bulgaricus* contain only a small fraction of the number of living organisms that the manufacturers represent. Many of the preparations as sold at retail are sterile, containing no living bacilli of the bulgaricus type or any other living organism.

2. The majority of organisms as seen in a stained specimen are dead and hence are of no significance.

3. Broth cultures obtained direct from the manufacturers are the best preparations.

4. Tablets are useful if the product is to be conveyed a considerable distance. Some preparations of the tablets are potent, many are sterile, and some are heavily contaminated.

I desire to acknowledge my indebtedness to William H. Park, director of the laboratory of the New York Department of Health, for the material and for many valuable suggestions in the course of this work.

A MONILIA FOUND IN CERTAIN CASES OF SPRUE

PRELIMINARY NOTE

BAILEY K. ASHFORD, M.D., Sc.D.
Major Medical Corps, U. S. Army; President of a Board for the Study of Tropical Diseases as they Exist in Porto Rico, Collaborating with the Institute of Tropical Medicine and Hygiene of Porto Rico
SAN JUAN, P. R.

In the course of the study which I am making of certain cases of sprue in the laboratory of the Institute of Tropical Medicine and Hygiene, my attention has been called to the presence, in the four cases in which I have made cultures from the *inflamed* tongue, of a Monilia not described by Castellani and Chalmers,[1] or mentioned by Bahr.[2] My failure to find the organism in apparently normal tongues of convalescents from sprue has prompted me to write this preliminary note. In one case culture from the uninflamed tongue was negative, although the patient was desperately ill from one of the intestinal localizations of the disease so familiar to those who know sprue clinically. Only when the intestinal symptoms subsided and the tongue became inflamed was a successful growth obtained. This case has shown repeated and severe desquamatory inflammation of the tongue, so that persistent effort would have possibly demonstrated the organism in the deeper layers of the epithelium, even during the quiescent period. In the few normal tongues which I have examined I have not yet found this Monilia.

---

[1] Castellani, Aldo, and Chalmers, A. J.: Manual of Tropical Medicine, Ed. 2, New York, William Wood & Co., 1913.

[2] Bahr: Researches in Sprue, 1912-1914, Jour. Trop. Med. and Hyg., July 1, 1914.

Of the four positive results obtained, three were in children; one 12 years of age, in whose family mother, father and sister all give histories of recurrent exacerbations of sprue; one a child of 2½ years, whose clinical picture leaves no room for doubt and whose mother also gives a history of intestinal fermentation and inflammation of the mouth; and the third in an infant of 15 months, whose symptoms resemble thrush but in whom a tentative diagnosis of sprue must be entertained, because of the four months' duration of his stomatitis in spite of treatment, his repeated fermentative "indigestions," and the fact that his mother suffered from an aphthous stomatitis with violent inflammation of the tongue just previous to her baby's illness. The fourth is a typically severe case of sprue in a high official of the federal government, diagnosed by me over a year ago. On going North for a vacation he received a confirmation of that diagnosis from a former practitioner in the far East and now an instructor in tropical diseases in one of our Northern schools.

The salient features of the work so far done are as follows: Plate cultures were made of scrapings from the inflamed dorsum of the tongue, and the Monilia was thus isolated and planted in plain bouillon. After several days' growth the various mediums were infected. In the case of all liquid mediums, two tubes were incubated together, one infected and the other not. In the case of the sugar bouillons, three tubes were used for each; one fermentation tube, one litmus tube and one without litmus. This was done in order to determine accurately by titration the changes in reaction due to the culture. The method of standardization recommended by the Bacteriological Committee of the American Public Health Association was strictly followed. The mode of procedure was as follows: After fifteen days' incubation at 34 C. (93.2 F.) the two infected tubes of a given sugar medium were examined to see if contamination by bacteria had occurred. Then the infected medium of the fermentation tube was titrated, 5 c.c. to 45 c.c. of distilled water, using as an indicator 1 c.c. of a 0.5 per cent. phenolphthalein solution in 50 per cent. alcohol. The titration was carried out at boiling point and the same was repeated with the cold culture. The litmus tube was used, not so much for a control as for the purpose of watching the varying reaction during the course of the fifteen days' incubation. Care was taken accurately to titrate the mediums before infection, and all three tubes were filled with the same lot of mediums.

Litmus Milk.—Rendered alkaline; no clotting or decoloration.

Glucose Bouillon.—First few days strongly acid, with production of much gas. Thereafter litmus tube generally becomes blue and gas diminishes to a mere bubble. Titration, however, still shows neutral or a slight increase in the acidity over control.

Levulose Bouillon.—Much gas and is rendered acid. Gas diminishes to a mere bubble at the end of fifteen days.

Maltose Bouillon and Beerwort.—Same as for levulose.

Galactose and Saccharose Bouillons.—Rendered acid.

Lactose, Mannite, Dulcite, Dextrin, Raffinose, Arabinose, Inulin, Erythrite, Amygdalin, Asparagin, Isodulcite and Plain Bouillon.—All lose decidedly in acidity save mannite and dextrin, which are little changed as compared with the control.

Blood Serum.—On this a scanty, almost invisible white growth was distinguished. There was no brownish pigmentation, nor was the medium liquefied.

Gelatin.—On this there was a growth all along the stab, with fine brush-like villous extensions. It failed to liquefy gelatin even after two months.

Dunham's Peptone Solution.—On this no indol was produced, nor was the reaction altered.

Bouillon.—The growth on this was characterized, not precisely by the formation of a pellicle, but by a heavy collar at the surface, the result of the adherence of mycelial elements to the glass. This collar at times became a coriaceous pellicle resembling a false membrane, which in due time fell to the bottom of the tube, another being formed at the surface later on. In all bouillon cultures the medium remained clear, save for the sputum-like shreds and deposit.

Solid Mediums.—The growth on these is creamy white. At first the colonies are round, almost hemispherical, with even border sharply delineated from the mediums, but later these colonies rapidly run together and form a thick creamy white layer on the whole surface of the agar. All the sugar agars were sown, as well as potato and carrot, plain and glycerinized.

The growth on glucose, levulose, maltose and saccharose agar is exceptionally heavy, in the order named. The organism grows well on very acid mediums, even to + 4.5.

A hypodermic injection of a few drops of a ten-day culture in plain bouillon into the muscular tissue of the tongue killed a large rabbit in seventy-five hours. After forty hours, severe diarrhea came on with the production of much gas. Death occurred from general mycosis. The necropsy was performed one hour and a half after death, approximately, by myself and Dr. W. W. King of the United States Public Health Service, member of this institute. A necrotic spot was found in the tongue at the site of the injection, and a high grade of congestion of lung, liver and kidneys was demonstrable. All the serous cavities were found normal. A heavy creamy white mucoid coating was found on the stomach and small intestine. Cultures were made under the usual strict precautions against contamination, from liver, spleen, kidney, lung, the muscular tissue of the tongue, and the heart's blood, on Sabouraud's glucose agar slants, and pure cultures were directly obtained without the appearance of any other organism. As the animal accidentally received 1 or 2 gm. more by mouth, owing to the leaking of the syringe, cultures were made from the mucoid layer coating the stomach and small intestine, and an abundant growth was recovered. The details of the biologic study of this Monilia, together with feeding experiments in monkeys and other laboratory animals, will appear in a forthcoming report of the Institute of Tropical Medicine and Hygiene of Porto Rico.

The Ideal Commonwealth.—Our youth will dwell in a land of health, amid fair sights and sounds and receive the good in everything; and beauty, the effluence of fair works, shall flow into the eye and ear like a health-giving breeze from a purer region, and insensibly draw the soul from earliest years into likeness and sympathy with the beauty of reason.—Plato, Book III, of the Republic.

NITROUS OXID GAS ANALGESIA IN OBSTETRICS

J. CLARENCE WEBSTER, M.D.
CHICAGO

For many years chloroform and ether have been used to alleviate the pains of women in labor. Valuable as these agents are when deep anesthesia is required for the carrying out of operative procedures, they have not proved satisfactory as analgesic agents. It administered in small quantities at the commencement of a strong uterine contraction, the patient does not usually inhale sufficient to abolish pain. She is then apt to be irritated and is certain to insist on being given a larger quantity. If a sufficient amount be administered to satisfy the woman, the continued repetition gradually inhibits the power both of the uterus and of the accessory muscles, so that labor is unnecessarily prolonged, and, possibly, the life of the fetus endangered. Physicians have, therefore, been accustomed to employ these drugs very sparingly, restricting their use to the very end of the second stage, during the painful passage of the head through the vulva. The results of the administration at this time are also uncertain. If delivery be rapid the woman may not be able to inhale sufficient to abolish her consciousness of pain. If it be slow she may take too much and weaken the muscular powers, thereby prolonging labor and, often, necessitating forceps delivery. It is not surprising, therefore, that the medical profession has long been hoping that a more satisfactory method of relieving the pain of labor would be found.

Within recent years a new procedure, "made in Germany," has been introduced, consisting in the administration of scopolamin and morphin early in labor. In spite of the publicity which has been given to this so-called "twilight sleep" method by the lay press it has not found favor with the great majority of leading obstetric authorities in Europe or America. They are too well aware of the uncertain effects produced by the mixture and of the complications which may be caused, to adopt it. For many generations obstetricians have avoided the use of morphin, except in rare cases, because of its bad effect on the child and its interference with muscular activity in the mother. Scopolamin is variable and uncertain in its action and very often produces marked excitement in the woman, which may greatly interfere with carrying out of a clean technic. The lay press has not referred to the mental disturbances which have been produced nor have they made known that in that part of Germany where the procedure originated, a large number of damage suits have been instituted in the courts against prominent physicians, because of various ill-effects alleged to be due to "twilight sleep."

The advocates of the German method insist that it must not be used by the ordinary practitioner but by obstetric experts. Ordinary hospitals are not even considered suitable. Special chambers with luxurious and harmonious esthetic equipment, isolated and soundproof, doctors and nurses wearing noiseless slippers, speech carried on in quiet whispers—these are the accessories especially recommended for obtaining success with scopolamin-morphin.

We doubt the possibility of reaching success with it in an American city.

About ten years ago, in my service at the Presbyterian Hospital, I began to use nitrous oxid gas in certain complicated obstetric cases: for example, version, forceps-delivery, vaginal cesarean section and repair of lacerations. Later, I performed several abdominal cesarean sections in cases in which ether and chloroform were contra-indicated.

It was noticed that the administration caused no ill-effects to mother or child, did not affect the strength of uterine contraction or lead to post-partum inertia. On a number of occasions I employed the gas during the passage of the head through the vulva, in normal cases, relieving the patient's sufferings without interfering with the progress of delivery.

In recent years, as a result of the employment of nitrous oxid gas (usually with 3 per cent. of oxygen), as well as of local anesthesia, ether and chloroform have been much less employed than formerly.

During the past year a new departure has been made in the maternity service of the hospital, namely, the use of nitrous oxid in labor to abolish the pains caused by uterine contractions. Careful observations have been made by different members of the staff, including Drs. Lynch, Heaney, Davis, McCullough, Hixon and Wells. We are in entire agreement as to the complete success of the method in relieving women of the sufferings of childbirth. The technic is very simple. Usually the administration is begun when the patient complains of second stage pains, though it may also be used during the first stage. In the majority of cases, however, gas is not necessary during the greater portion of this period. It is very important that women should not be educated to regard labor as a terrible experience, something akin to a surgical operation, necessitating the free use of anesthetics. The large proportion of patients suffer comparatively little severe pain. Very often the support and encouragement of a judicious physician or nurse have a marked effect in subduing nervousness and distress. It is to be hoped that the new movement in obstetrics will not result in destroying courage, self-reliance and endurance in our women. The apparatus is that ordinarily employed by dentists.

It has been found best to use a small nasal inhaler, the mouth of the patient being uncovered. The gas-bag attached to the tank is kept under low pressure and, as the pain begins, the patient is instructed to breathe quietly, keeping her mouth closed. Ordinarily, light inhalation suffices to produce the analgesic effect. It is not necessary to cause asphyxiation or jactitation, which are due to the inhalation of large quantities of gas. Expulsive efforts on the part of the patient are not interfered with, to any appreciable extent. As soon as the uterine contraction begins to subside the inhaler is removed and the patient is again conscious. This procedure may be kept up for hours if necessary. A nurse or assistant may be instructed so as to carry out the administration satisfactorily.

Pure nitrous oxid gas or gas with oxygen (3 per cent.) may be employed. The former is, perhaps, most universally applicable. It may be used in private houses as well as in hospitals, the necessary apparatus being small, compact and easily transported.

The amount of gas varies according to the duration of painful contractions, and the cost is therefore a variable factor. In the Presbyterian Hospital the ordinary small gas-tanks have chiefly been used, the expense of administration being comparatively small. In hospitals where large tanks may be employed, the cost may be reduced about one-half. Of course it is necessary to be careful not to waste the gas.

From our experience in the Presbyterian Hospital, this method is recommended as the safest and simplest method of conducting painless labor.

Its advantages are as follows:

1. The apparatus is simple, easily transported, and may be used by any practitioner.
2. Deep anesthesia is not necessary.
3. There are no ill-effects to mother or child.
4. The strength of uterine contractions is not diminished, no matter how long the administration of the nitrous oxid gas is continued.
5. The administration is under control all the time, and can be stopped at any moment. This is a very decided advantage which is not possessed by any method which necessitates placing a patient under the influence of drugs administered internally.

NITROUS OXID GAS ANALGESIA IN OBSTETRICS

FRANK W. LYNCH, M.D.
CHICAGO

Nitrous oxid in anesthesia has become most popular during the last few years. Gas and ether machines have undergone marked improvements. Their use in surgery and dentistry is well-nigh universal. Analgesia has supplanted anesthesia in a considerable field of surgical work. Analgesia is obtained during the first stage of anesthesia. It is the stage of *Dammerschlaf,* the threshold of sleep, in which stimuli to the skin cause no mental impression, and consciousness is disordered.

Since July, 1913, I have used gas for long-continued analgesia in my obstetric work. The method should not be confounded with the old and well-known use of gas during the past generation, given to deeper stages of anesthesia about the time of actual birth. The results obtained by this new method have been astonishing. There is freedom from pain. There are no bad effects for mother or child. The gas in analgesic doses appears to stimulate the uterine pains. There is no doubt of the patient bearing down more energetically when under the influence of the drug. I made mention of the method at the Michigan State Medical Society at Flint, Sept. 1, 1913.[1]

I have used the method for more than one hour in thirty-four cases. Analgesia has been maintained from the latter part of the first stage, or from the time when the pains became severe; and all have said that pain was negligible and practically nil. There are twenty-five primiparas and nine multiparas in the series. Analgesia was continued in thirty-four cases more than one hour; in thirty-two cases more than two hours; in twelve cases more than three hours; in four cases more than four hours, and in one case more than six hours. Three cases were terminated with forceps with the gas carried to surgical degree. They were all primiparas, one of 39 years, one of 35, and one of 25, in whom there was transverse arrest of the head. There was no case of inertia, post-partum hemorrhage or shock.

The method is suitable for patients at their homes or in the hospital. Any gas machine with a Hewett stopcock permitting the admixture of oxygen and gas will do. I use a small portable machine, which holds four tanks. The best results are obtained with a nose-piece such as is used by dentists, but the ordinary mouth-piece will answer. I have hitherto started the treatment when the pains have become severe enough to occasion complaint. Pure nitrous oxid gas is turned full on at the beginning of the pain, and the patient is told to breathe deeply but rapidly through the nose. Five or six respirations suffice to produce analgesia, even in the presence of the uterine contraction. The nose-piece is now placed over the mouth. The patient is told to breathe through the mouth, and analgesia is maintained by admixing oxygen with the gas until the end of the pain. This process is repeated with each pain. The percentage of oxygen varies from nothing to 10 per cent. It is more difficult to maintain analgesia with the mouth-piece without wasting much gas, since the depth of anesthesia is now more difficult to control. Oxygen must be used more freely. When the head distends the perineum, the anesthesia is carried to the surgical degree, and the color of the patient is controlled with oxygen. Separate tanks of gas and oxygen are best and cheapest. Their small size admits of easy transportation. Separate tanks permit the variations of percentage of oxygen. With these small tanks the method costs from four to five dollars per hour, varying with the duration and frequency of the pains and the skill of the operator.

Gas is the ideal drug for conducting labors. It is the most volatile of anesthetics, acts most quickly, and its effects pass away most rapidly. It is practically free from danger even when continued for analgesia of many hours. This may be evinced from the work of Woodyatt.[2] A number of dogs were sensitized to toxins by removal of their glycogen. No animal thus treated survived ten minutes of chloroform narcosis. There were marked changes in the secretions of the dogs anesthetized for the same period with ether. Yet two hours of anesthesia with nitrous oxid caused no demonstrable tissue injuries, and the changes in the secretions were trivial or nil. Theoretically, therefore, we may expect to continue analgesia throughout the entire labor, with trivial resultant injury. Nor does the drug cause, as chloroform, lesions of the fetus, since there is no resultant tissue asphyxia on which are dependent the visceral and hemorrhagic diseases of the new-born (Graham).[3]

This method is not original with me, and was first seen July 12, 1913, in a case which I saw with my colleague, Dr. Junius Hoag. The patient was the daughter of Mr. Clark, a maker of instruments for anesthesia, who had sought at his own risk to try in his family the method which his demonstrators were teaching for dentistry. The analgesia was maintained for four hours, with anesthesia to surgical degree, for purpose of delivery. The method was also independently developed by Dr. Heaney about six months later, who tells me he has a considerable series of cases about ready for report. He is likewise most enthusiastic over the method.[4]

I am of the belief that this will make the use of scopolamin-morphin unnecessary in the treatment of private cases. Its ease of administration and freedom from danger speak volumes for its popularity. Nor is the technic complicated or the good results limited to one man. Unlike the Freiburg method, it is adapted to work in the private home, and is devoid of its many dangers.

LEAD POISONING FROM THE USE OF COSMETICS

TWO CASES OF THE NEUROMUSCULAR TYPE

G. WILSE ROBINSON, M.D.
KANSAS CITY, MO.

Many monographs have been written concerning industrial lead poisoning. It is quite generally understood that file making and jewel polishing, the making of cheap kitchen ware and the polishing of cut glass, are notoriously dangerous trades in Europe. In the United States, workers who rub with sandpaper the newly painted bodies of railway coaches, carriages and automobiles, the laborers in white lead factories and the makers of storage batteries or electrical accumulators, because of non-protection, are in more danger of lead poisoning than are those who work at the same trades in Europe.

It is my desire to call attention to a form of lead poisoning other than industrial, which I believe to be quite common, and which in my opinion impairs the health and lessens the efficiency of a not inconsiderable number of our female population.

There are three channels by which lead may enter the body: the skin, respiratory passages, and alimentary canal. Of these three channels of absorption the former is least and the latter the most important. However lead enters the body, it may impair the structure and disorder the function of any of the organs and tissues. It destroys the blood cells, causes arteriosclerosis, accumulates in the liver causing fatty degeneration of the hepatic cells, hinders the normal intestinal peristalsis, but its baneful influences are exercised principally on the kidneys and the cerebrospinal nervous system. It causes a parenchymatous, followed by an interstitial, nephritis, seriously impairing the function of the kidneys.

The nervous system is especially prone to be affected by lead. The most dangerous and fatal form of lead poisoning is the cerebral type, which has been termed lead encephalopathy. Epileptiform convulsions constitute the most prominent symptom. Death may follow very shortly the onset of such convulsions, or the patient may recover to be totally blind or deaf. Neuroretinitis may occur without any concurrent kidney disease. This is another serious and grave type of plumbism which may be accompanied by epileptiform convulsions. Hysterical manifestations may develop from lead poisoning, as may a condition resembling general paralysis of the insane, delirium, coma, and hemiplegia. Under the influence of lead intoxication, the pyramidal cells in the ventral horns of the spinal cord may degenerate giving symptoms of poliomyelitis. A type of muscular incoordination which has been designated pseudotabes is of not uncommon occurrence.

Of the various neurologic manifestations of plumbism, the neuromuscular type is the most common. There are two factors operating to produce this condition. First, the direct presence of the lead; second, the retention in the system of toxins because of the hypofunctioning of the excretory organs, for which the lead is responsible. The pathology has not been definitely determined. Some believe it to be central and of the nature of poliomyelitis, others contend that it is entirely peripheral and of the nature of a neuritis. The most common form of the neuromuscular type is symmetrical wrist-drop due to paralysis of the extensors of the wrists. The patient usually experiences pain or numbness in the muscles of the forearm and leg and generally a few attacks of colic, and suddenly or gradually loses the power of extending his wrists. It is usually bilateral and atrophy generally follows.

While simple wrist-drop with paralysis of the extensors is the most common form of neuromuscular type of lead palsy, other types do not infrequently occur. The scapulohumeral type involving the shoulder girdle and humerus, occurs occasionally. All the muscles of the shoulder, arm, forearm, wrist and hand may be paralyzed symmetrically. The muscles of the lower extremities are not commonly paralyzed as the result of lead intoxication, but a peroneal type of paralysis occasionally occurs. The muscles chiefly affected are the long extensors of the toes and the peroneals, the anterior tibials escaping. This type of paralysis is more frequently met with in children than in adults. In the more chronic types of lead intoxication, the paralysis, occasionally, either slowly or quickly extends to all the muscles of the limbs, hands, feet and even of the trunk. In these cases the symptoms are commonly those of multiple neuritis. The paralysis is either accompanied or followed by muscular atrophy, the muscles usually giving the reaction of degeneration. It is commonly preceded by colic, numbness of the fingers and toes and may be accompanied by pains in the extremities. In one type of generalized form, the deep reflexes are exaggerated and the extensor toe phenomenon is present. This is called the amyotrophic type, but ordinarily the deep reflexes are lessened or absent and the extensor phenomenon is not present.

The following case reports are chiefly interesting because of the manner of entrance of the lead into the system.

CASE REPORTS

Case 1.—B. F., aged 22, single, seamstress, consulted me in 1912 concerning a paralysis of the upper extremities. Family history of no special interest. Past history, usual diseases of childhood; generally healthy. Had been a seamstress for some years. Had no serious illness. All functions had been normal up to a few months previously. Present illness began two months previously. Had numbness and tingling sensation of fingers for a short period. Onset of paralysis was gradual. Atrophy accompanied paralysis. Was not painful and was not preceded by colic.

Examination.—Well developed young woman; actual and apparent age about the same; no disturbance of functions of special sense organs. Thoracic and abdominal organs apparently in a normal state, excepting for slight constipation. Trunk and lower extremities normal in every particular, slight blue line on gums; muscles of shoulders, arms, extensors of wrists and hands paralyzed and atrophic. Very slightly decreased appreciation of prick and tactile stimuli over these regions.

Diagnosis.—Lead intoxication with a combination of scapulohumeral and wrist-drop type of neuritis. Patient alleged she had had no chance of getting lead into her system in any manner. I suspected that holding lead dyed thread in the mouth while sewing was responsible. On further investigation I found that the patient had for some years been using a cheap face powder called "Flake White." The "Flake White" as sold for this purpose is a levigated subcarbonate of lead and is rubbed on the face with a moist sponge.

Treatment.—The use of "Flake White" was discontinued, iodids and salines administered, and the patient recovered within a few months.

Case 2.—I. H., aged 24, widow, housekeeper, consulted me in 1913. Complaints: Generalized pain, paralysis and muscular atrophy. Family history of no special interest. Past history disclosed the usual diseases of childhood; generally well until the last three or four years. Her husband lived but a short time after marriage. She gave vague history of what she called rheumatism. Had similar attack three years previously, from which she recovered. Three months previously the patient was operated on for appendicitis, or rather was operated on because of pains in abdomen supposed to be appendiceal in character. Operation did not reveal appendicitis. The cause of pain was not determined at that time.

Present illness began three weeks previous to the above date. First with cramping in abdomen, pain and numbness in extremities. Extreme constipation; loss of appetite; hands and arms became weak. After weeks' duration the pain became worse in shoulders and arms and this was quickly followed by complete paralysis. The first symptom of paralysis observed was wrist-drop, which steadily grew worse; legs became weak and painful, until the patient was scarcely able to walk.

Examination.—Woman about 25, of the brunette type, apparently poorly nourished and somewhat emaciated. Appeared to be quite anemic. Organs of special sense functioning in normal manner. Tongue heavily coated; heavy blue line on gums. Muscles of entire upper extremities showed atrophy; tender to deep pain stimuli, and deep reflexes absent. Some lessening of response to the tactile and affective components of sensation, superficially. Reaction of degeneration present. Muscles of lower extremities generally somewhat wasted, much lessened in power, skin slightly anesthetic and analgesic; increased response to deep pain stimuli. Deep reflexes decreased. Arteries slightly sclerotic, blood pressure 160 and 105. Respiratory organs normal; red blood cells 4,040,000; white 12,800; hemoglobin 60 to 70. Examination showed many stipple cells. The urine contained lead.

Diagnosis.—A generalized form of lead neuritis. Wassermann reaction of the blood was positive; patient denied venereal history, and no other evidences of syphilis could be obtained. It is worthy of note, however, that it is not unusual to get a positive Wassermann in lead intoxication. This was obviously lead intoxication with generalized lead neuritis.

A question again arose as to how the lead got into the system. Diligent inquiries revealed no known means by which lead had been absorbed or consumed. When asked about face powder used the patient said she had been using "Flake White" since a small child and that her mother and grandmother had used the same form of face powder. An examination of a sample of powder in possession of the patient showed it to be levigated subcarbonate of lead. I assumed that the lead had been absorbed from the skin as the result of the use of this powder.

Treatment.—Patient was given ox-gall, iodids and salines, the ox-gall for its biliary stimulating properties, the iodids to dissolve the lead out of the tissues, and the sulphate of magnesia and soda to combine with such lead as might enter the gastro-intestinal canal and prevent its reabsorption. The patient improved very slowly, but when she passed from under my care was much improved though still not well. I have learned that she has continued to improve.

These patients represent two rather extreme types of lead intoxication due to skin absorption from a cosmetic. This face powder is and has been for years in general use, and it is my opinion that as a result of its use, many women suffer from lead intoxication of varying degrees, causing in them anemia, debility, constipation, etc., and perhaps nephritis.

I believe many cases of general nervous debility, some of insanity and perhaps other types of paralysis are caused by the use of cosmetics containing lead. I am convinced that lead absorbed in this manner is an important contributing factor in impairing the health and lessening the general efficiency of a considerable number of women.

Many of the vague and not understood abdominal pains are due to this cause. I believe abdominal sections are done because of lead colic, and some appendices removed for the same reason. Lead causes abortion and doubtless some of the unexplained abortions could be accounted for in this manner. The public should be warned against the use of "Flake White" as a cosmetic, and its sale for this purpose should be prohibited.

Rialto Building.

REPORT OF CASE OF TETANUS

T. H. KELLEY, M.D.
CHICAGO

The following case is reported to add corroborative testimony to the efficacy of intraspinal administration of tetanus antitoxin as outlined recently by Park and later by Irons.

History.—Harry K., aged 11, a schoolboy, on November 10 was struck by an automobile while crossing the street, sustaining several lacerations. One, a deep gash above the ankle, was closed with about twenty silkworm-gut sutures. The other laceration, at a slightly higher level, was superficial.

November 19, the boy complained of a stiffness of the jaw which was easily apparent on examination.

November 20, a few slight convulsions were noticed.

November 23, no treatment given until this date, when 1,500 units of tetanus antitoxin were given intramuscularly.

November 24, the boy was unimproved and the dose previously given was repeated intramuscularly. The case was now referred to me by the family physician and the patient sent to the hospital.

Examination.—This showed a pronounced case of tetanus. The jaws were firmly set; a typical risus sardonicus and marked opisthotonus were present. Convulsions occurred about every fifteen minutes and were precipitated and intensified by the slightest noise.

The wound on the leg presented a dirty, ulcerating inflammatory appearance.

Urine: Acid; specific gravity 1.026. No albumin, sugar or casts. No blood count was made. Temperature, 101.4 (rectal), pulse, 120, respirations, 24.

Treatment.—Patient was taken to the operating room and anesthetized with gas and ether. Fifteen hundred units of antitoxin were given by the intraspinal route. The same amount was given intravenously. During the balance of the day no change was noticed in his condition. At the end of the day he had spasms quite frequently, necessitating the use of chloroform.

November 25, another injection of 3,000 units of antitoxin was given both intraspinally and intravenously. Spasms were quite marked during the day, and, as on the previous days, morphin and chloroform were administered at intervals. Toward evening the history notations indicate that the spasms became easier and shorter in duration. Pulse noted as stronger though rapid. Temperature, 101.2 (axillary). Pulse, 126.

November 26, spasms easier. Tendency to rest but still disturbed by spasms of short duration.

November 27, patient much better. Could take sponge bath with ease. Temperature 99.8, pulse 108.

November 30, the boy could turn head and body with comparative ease. Was disturbed only occasionally by twitching. Trismus much improved. Temperature, 98 (axillary); pulse, 88.

December 2, no evidence of twitching recorded. Could use back rest.

December 8, patient was allowed to be taken home, convalescing nicely. When he left the hospital the stiffness of his jaw, which was the last symptom to commence clearing up, was practically gone. He has progressed uneventfully since this date.

In connection with this case it is to be noted that the period of incubation was nine days, which thus classifies it as an acute case. It was allowed to reach an extreme state with convulsive seizures occurring every fifteen minutes. Forty-five hundred units of tetanus antitoxin were slowly injected intraspinally according to the usual technic. Forty-five hundred units were given intravenously, which is somewhat below the amount usually deemed necessary. No antitoxin was given by the subcutaneous or intramuscular routes except the 3,000 units given before the patient was brought to the hospital.

The local treatment consisted in exposing the wound to a continuous stream of oxygen for thirty-six hours. Boric acid and alcohol dressings were used to counteract the local infection. Free use was made of cathartics. During the first two days in the hospital sedatives in form of morphin and chloroform were at intervals used. It would appear that in the intraspinal administration of tetanus antitoxin we have an agent that has robbed lockjaw of its despairing terrors.

HYDROCEPHALUS

THE POSSIBLE RELATION OF A CONTRACTED PELVIS TO HYDROCEPHALUS DEVELOPING AFTER BIRTH

RUDOLPH J. E. ODEN, A.B., M.D.
CADILLAC, MICH.

While it is recognized that an obstruction of the foramen of Magendie or the aqueduct of Sylvius will cause hydrocephalus, yet, in searching the literature at my command I have failed to find an instance in which reference is made to delivery through a contracted pelvis as a possible cause of these lesions. For the present I wish to eliminate the developed congenital type of hydrocephalus and consider only those cases which appear normal at birth, but soon thereafter show abnormal cephalic development.

The pathologic findings of an advanced hydrocephalic, that is, the overdistended ventricles and their sequelae, require no reference in this connection, but the primary factors, that is, the occlusion of the foramen of Magendie or the aqueduct of Sylvius, do furnish special interest. The method of their occlusion, whether it be of an infectious or a mechanical nature, should be accepted as the primary factor for consideration.

I find but one instance[1] in which hydrocephalus was produced in the laboratory by mechanical obstruction, but the results from these tests were sufficient to demonstrate that a blocking of the ducts hindered a normal communication between the ventricles; that practically no absorption occurred in the ventricles, but on the contrary, a secretion of fluid which in time filled the isolated chambers to overdistention.

Accepting the foregoing, the possibility of a contracted pelvis causing abnormal compression of the child's head sufficient to occlude, if not obliterate the duct, would not be out of reason. The idea may seem far fetched, however, when the anatomic relations of the structures are considered. Not infrequently a child appears normal after a difficult labor, but soon thereafter portrays symptoms of hydrocephalus.

Lues and tuberculosis are usually considered as the causative factors when the condition occurs, but we are beginning to learn that these diseases are not responsible to the extent that was formerly believed. In fact, repeated complement-fixation tests[2] speak against the assumption of syphilis as a common etiologic factor.

An instance in which two successive children developed post-partum hydrocephalus, when both parents were free from stigmata of disease, but pelvic mensuration of the mother revealed a contracted pelvis, is of interest in this connection. A third child, delivered through a cesarean section, showing no abnormal symptoms several months later, lends additional interest, and is sufficient to serve as a forcible argument for the possibility of a contracted pelvis being the prime causative factor in many cases of post-partum hydrocephalus.

History.—Mrs. D., aged 29, well nourished; past history negative. Same is true of husband. Patient the mother of four children, two living and two dead. The first child was an undersized babe at birth, now eight years ago. Although the labor was very difficult, still it terminated normally. The child is to-day healthy in all respects.

The second child, born three years later, reached full term. The patient says that it was a very difficult and prolonged labor, terminated by instrumental means. The child appeared normal at birth, but shortly thereafter began to develop hydrocephalus. It lived three years. It was my privilege to see this little patient shortly before he died. I regret not having secured a photograph, as the case showed such a pronounced state of development. No complement-fixation test was made.

The third child was delivered under most difficult circumstances. He lived but a short time; at birth there were no symptoms of cephalic enlargement, but it was well marked at death.

A fourth pregnancy reached full term. In the meantime a pelvic mensuration had revealed a contracted pelvis. The patient had been in labor twelve hours when I was called. I found the os well dilated, and fortunately the sac was still intact. No engagement had taken place. She was removed to the hospital where I performed a cesarean section and delivered a normal child. The steps of the operation need not be mentioned here. The mother made an uneventful recovery. The child is to-day, four months later, apparently healthy and shows no signs of any abnormal cephalic development.

It would be rather presumptive on my part to infer that this child would have developed hydrocephalus, as did the two previous children, as there is of course no proof to substantiate this assumption, but the coincidence of the contracted pelvis and the fact that the last child is healthy and normal is sufficient to point toward the possibility of the previous labors being the prime causative factor in the two former cases. Be that as it may, the case is undoubtedly of sufficient worth to serve as a guide for other similar cases, if not of argumentative worth.

All the ingenious methods of von Bramann[3] and others to establish a communication between the two ventricles, are far from satisfactory. Here as elsewhere, if prevention is possible, it is far better than cure. The operation of cesarean section, when performed by a surgeon ready to cope with conditions as they arise, is not a formidable one, and is truly justifiable in later pregnancies when there is a contracted pelvis, and hydrocephalus has developed after a previous difficult labor. In case the hydrocephalus has developed in utero, the operation ought to be the procedure of choice as the barbaric operation of craniotomy is truly a more hazardous one, so far as the mother is concerned, than is cesarean section. As to the method employed, whether it be the classical section or the extraperitoneal, is of course optional with the surgeon. Both methods have their advantages.

REPORT OF FOUR CASES OF FOREIGN BODY IN THE AIR PASSAGES OR ESOPHAGUS *

G. W. BOOT, M.D.

CHICAGO

Case 1.—*Jackstone in the Larynx.*—F. B., boy, aged 19 months, got a "jack" in his throat a month before admission to the Children's Memorial Hospital. He was playing on the floor when his mother picked him up to change his diaper. As she picked him up he grasped a couple of jackstones with which the other children were playing, and as his mother laid him on his back he dropped them. One of them went into his mouth. The mother took him at once to a hospital where some physician, probably an intern, assured her that there was nothing in the child's throat. He passed a stomach tube and told the mother that if the jack were in the throat the stomach tube would shove it on into the stomach.

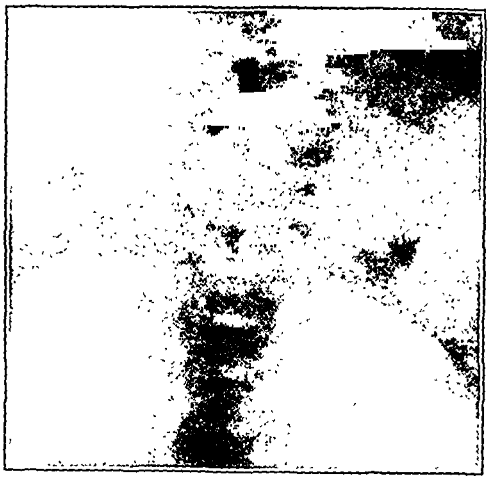

Fig. 1.—Jackstone in the larynx (Case 1).

The child's difficulty in breathing and swallowing continued so that she returned with the child to the hospital the next day. This time she says she was told that the child in all probability had a "cramp." She next took the child to the family physician, who treated the child for bronchitis.

After a month he was brought to the Children's Memorial Hospital, where a roentgenogram was taken and the jack located. During the four weeks that the foreign body had remained in the child's throat he could eat very little.

On admission to the Children's Memorial Hospital his condition was fair. Breathing was difficult. The eyes, ears and nose were negative. In the neck there were palpable glands and distinct tenderness around the trachea. Examination of the chest showed difficulty in breathing, particularly on inspiration. The lungs and abdomen were negative. The roentgenogram showed the jack lying opposite the fourth, fifth and sixth cervical vertebrae (Fig. 1).

The patient was anesthetized with ether, and Bruening's speculum for direct laryngoscopy in children was introduced. On account of swelling at the entrance to the larynx, there was considerable difficulty in seeing the foreign body, although it could be easily felt with the speculum. Several attempts at grasping it proved unavailing; the speculum was removed and the foreign body grasped with a long pair of hemostats guided by the sense of touch. It was firmly imbedded and required some little manipulation and force to dislodge it. Only slight bleeding followed. The jack was so lodged that one of the ball-shaped ends was directed downward and lay within the lumen of the larynx. Another arm was directed backward, and lay between the arytenoid cartilages. The third arm lay crosswise within the lumen of the larynx, but above the vocal cords. The swelling of the aryepiglottic folds caught this arm, which was directed crosswise, and made the removal difficult.

The patient did well following the operation. He had a little fever for about three days. At one time he had so much difficulty in breathing that intubation was considered, but this cleared up without the necessity of intubating, and the patient was allowed to go home. He was somewhat hoarse when he cried, but otherwise he seemed well. Two days later he was brought back to the hospital with great difficulty on inspiration. I attempted to intubate but without success. The patient's condition in spite of inhalations of oxygen being very bad, I did a hurried tracheotomy without anesthesia. The day following the tracheotomy, the temperature reached 103, but declined soon afterward to 100. The next day it was normal. The tracheotomy tube had been in place one week and I was just ready to remove it when I was taken sick with scarlet fever and did not see the patient for six weeks. Meanwhile the tracheotomy tube had not been removed. When I removed the tracheotomy tube after it had been seven weeks in the trachea, the tracheal wound closed at once and no air could enter. The trachea was deformed by the long presence of the tube so no air could enter by the natural way. It was necessary to reinsert the tube at once to prevent death from asphyxia. Again I attempted intubation, but for some reason could not enter the larynx. It was necessary to enlarge the tracheotomy wound, but this could not be done with the tracheotomy tube in place on account of the flange on the tube. Accordingly the end was cut off a linen catheter the size of the tracheotomy tube, and this piece of catheter inserted instead of the tracheotomy tube. The tracheotomy wound was then enlarged and a very small linen catheter passed upward through this wound through the larynx until it could be drawn out of the mouth. The intubation tube was then threaded on this small catheter as a guide and shoved down until it reached the tracheotomy wound, when both catheters were removed and the tube pushed down past the wound. The wound was then allowed to heal, and in a week's time it was completely healed. The intubation tube was then removed, and the patient having no further difficulty, was discharged cured.

Among the interesting features of this case are:

1. The length of time a foreign body of this size remained in the larynx without causing alarming symptoms.
2. The ease of diagnosis by means of the Roentgen ray.
3. The difficulty of intubation.
4. The difficulty of establishing normal respiration after removal of the tracheotomy tube.

Case 2.—*Bronchoscopy with Removal of Tack from the Right Bronchus.*—C. A., boy, aged 9, deaf-mute, was said to have swallowed a nail about 7 o'clock in the evening. Immediately afterward he had a coughing spell which lasted for a half hour. At 10:30 p. m. he was brought to the Children's Memorial Hospital and roentgenograms taken showing both frontal (Fig. 2) and lateral views of the chest. The pictures showed a foreign body resembling a nail 1 inch long with a rather large head lying behind the sixth rib, 1 inch in front of the vertebral column, and ¼ inch to the right of the margin of the sternum. The shadow showed the point uppermost.

I saw the boy about 1 a. m. of the following morning and had him prepared for immediate operation. He was resting quietly at the time. He was anesthetized with ether and a low tracheotomy done, after which a suitably sized bronchoscopic tube was introduced and the nail found in the right bronchus lying with its point uppermost and caught in the tissues. I succeeded in getting the point dislodged and within the point of the bronchoscopic tube, where it was easily seized and withdrawn as far as the tracheotomy wound. Here the forceps slipped off, but fortunately my assistant caught the tack, as it proved to be, and prevented its slipping back into the trachea until I could grasp it with a pair of hemostats and remove it.

---

* Presented by invitation before the Chicago Pediatric Society, Nov. 13, 1914.

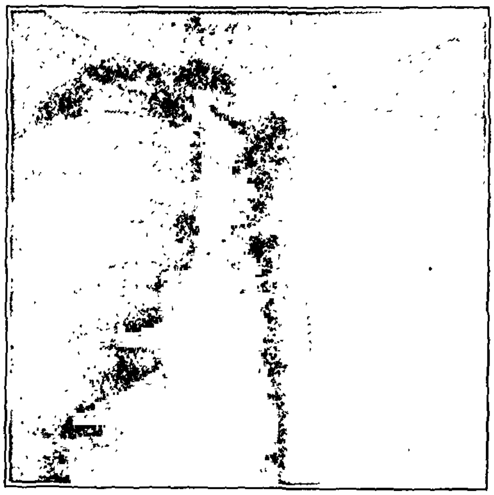

Fig. 2.—Tack in right bronchus (Case 2).

During the operation the trachea was stitched temporarily to the skin on either side with silk. At the close of the operation the stitches were cut and the parts allowed to fall back into their normal position.

The wound was packed lightly with sterile gauze, and the patient put back to bed. There was very little bleeding from the bronchus or trachea, and very little traumatism produced.

The foreign body was found to be an upholsterer's brass headed tack 1.8 cm. long, with a head 8 mm. in diameter. No cause for the deaf-mutism could be found in the history. He has one brother who is also a deaf-mute. Patient is said never to have given any sign of hearing.

Following the operation the course was uneventful, and the patient was discharged from the hospital in two weeks with the wound healed.

This case was suitable for upper bronchoscopy, and under similar conditions in a hearing patient I would do an upper bronchoscopy; but in this case, because we could not communicate with the patient, nor he with us, it seemed advisable to follow the method most certain to succeed at first trial.

The fact that the tack caught in the tissues with the point uppermost might have led to serious trouble in a careless or forcible removal.

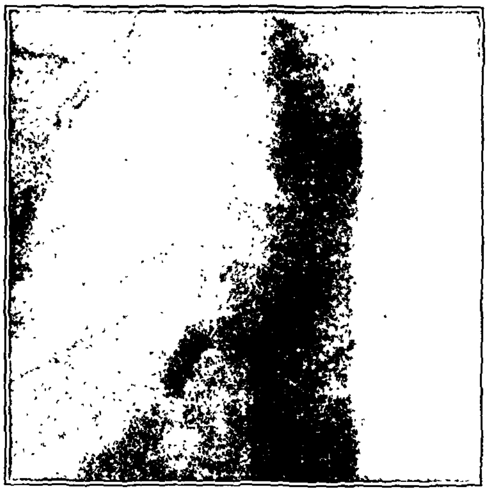

Fig. 3.—Brass arrowhead in left bronchus (Case 3).

Case 3.—*Arrowhead in a Secondary Division of Left Bronchus over Ten Months.*—W. T., boy, aged 10, aspirated the brass tip of a toy arrow, Jan. 2, 1914, and immediately had a severe coughing spell. From this time on he suffered with cough. On two or three occasions he had fever and was confined to bed for two or three weeks at a time.

He was treated by various physicians for bronchitis, tuberculosis, etc. About the last of April his father took him to Germany in the hope of finding some one who could relieve his troubles but found no one. Finally after his return to Chicago he was taken to the Children's Memorial Hospital, where a roentgenogram was taken (Fig. 3) and the diagnosis made by the patient as soon as he saw the picture. He pointed out the shadow of the arrowhead before any one else could say a word.

Following the correct diagnosis, I was called on to remove the foreign body. I attempted it at first under ether by the upper method. As soon as the bronchoscope passed the vocal cords, the patient stopped breathing, and it was necessary to remove the tube before he again began to breathe. When breathing had been resumed, another attempt was made to do upper bronchoscopy, but again he stopped breathing, and it was necessary to desist.

A low tracheotomy was then done and lower bronchoscopy attempted, but the patient did so poorly under ether that it was necessary to stop and wait for more favorable circumstances. A tracheotomy tube was inserted, and after a week an attempt was made under local anesthesia. The left bronchus and all its divisions and subdivisions that could be found were inspected and probed, but nothing found. Again it was necessary to stop.

Following this attempt, the patient's temperature ran up to 103, and it looked as if he were going to have an attack of pneumonia; but in a few days, under the administration of guaiacol carbonate, his temperature declined to normal, and a week after the second attempt, a third attempt was made under local anesthesia. This time the patient was given a hypodermic injection of 1/10 grain of morphin sulphate with atropin before the operation. At 10 per cent. solution of novocain was first sprayed into the trachea and later applied with a swab of cotton. The bronchoscope was then introduced, but as soon as it entered the left bronchus he had a severe coughing spell, and this cough could not be controlled until I had painted this area several times with a 5 per cent. solution of cocain. Finally, the coughing being controlled, all the secondary and tertiary divisions of the left bronchus were examined and nothing found. Finally, the bronchoscope being moved a short distance to the point where coughing had been excited, a small area of granulation was seen at the bottom of the tube. I attempted to brush this aside with a probe, and thought I saw the entrance to a secondary bronchus that I had not seen before. I passed a probe into this secondary bronchus, and thought that it touched a metallic body. The patient said he heard it touch. I then passed the expanding forceps into the same bronchus, opened it and withdrew it only to find that I had nothing. After swabbing out the bloody mucus I saw the edge of the arrowhead. I had drawn it partly out of the secondary bronchus and into the main bronchus, where it was easily seized and removed. Following the removal the patient's temperature rose 0.4 degree for a day. The second day it was normal and he was allowed to be up. At the end of five days the wound was so far healed that he was allowed to return home.

This case shows how a foreign body may cause pneumonia and symptoms of tuberculosis. It indicates how in chronic cases of lung disease, a roentgenogram or bronchoscopic examination may clear up the diagnosis. If the foreign body is opaque to the Roentgen ray, the picture is enough. If it is not opaque to the Roentgen ray, a foreign body may be found on bronchoscopic examination.

It is remarkable that a foreign body of this size, shape and composition did not make more lung symptoms. It must have acted as a ball valve, and the signs of atelectasis should have been present. They were not found.

This case shows well how in a difficult case of foreign body in the bronchi it is well not to keep up the examination too long. It is better to stop short of danger to the patient and to repeat the examination at a later date. It also shows the advantage of local over general anesthesia. A roentgenogram showed that the arrowhead had moved between the time of taking the first picture and the third examination. It looks as if the foreign body had been touched by the bronchoscopic tube in one of the first two examinations and pushed a little farther down.

Case 4.—*Open Safety Pin in the Hypopharynx.*—A boy, aged 19 months, got an open safety pin into his throat. He was brought to the Children's Memorial Hospital and a roentgenogram taken (Fig. 4). The pin could not be seen in the throat on ordinary inspection, but it could be felt on passing a finger down the pharynx. I seized the point with a long hemostat and disengaged it, guided by the sense of touch. Then while my finger rested on the point of the pin, the patient retched and forced the pin into the oropharynx, where it was easily removed.

This was an easy case for operation. The only danger was from the point of the pin. As soon as the point was disengaged, the patient did the rest. This pin caught at the first point of narrowing of the esophagus, and because of the point catching in the tissues, it could not be regurgitated. I am always anxious about these cases because the trauma to the esophagus may give rise to emphysema or to septic infection of the mediastinum, as in a case I saw with Dr. Friedberg, in which a general practitioner had attempted to push a bone on into the stomach with the result that he pushed it through the wall of the esophagus, where the septic infection caused the child's death.

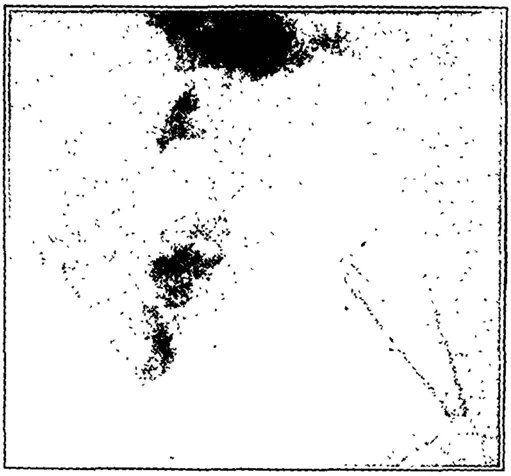

Fig. 4.—Open safety pin in hypopharynx (Case 4).

Taken as a whole, these cases show the very great aid to diagnosis given by the Roentgen ray. They also show what can be done by bronchoscopic methods in a class of cases that not many years ago were almost without means of relief.

122 South Michigan Avenue.

Rochester Life Conservation Plan.—Rochester has inaugurated a health campaign which it calls the "Live a Little Longer" plan. It originated with the board of education and consists at present in the employment of a nurse and a physician, who are to give in the various school buildings of the city two lectures each week for six weeks on all sorts of health and life conservation topics. The lectures are to be given in the afternoons after regular school hours and are open to all persons over 18 years of age. The plan has the support not only of the education body, but of the energetic chamber of commerce and other civic organizations and has the endorsement and active cooperation of the local representatives of the life insurance companies represented in Rochester, who have already sent out circular letters calling attention to the well planned course of instruction in health matters following the approval of the companies of the plan. It is hoped by the originators of the plan that it may become general throughout the country.

A SPECIMEN OF CONGENITAL INGUINAL IMPLANTATION OF THE VERMIFORM APPENDIX*

H. WINDSOR WADE, M.D.
NEW ORLEANS

It need scarcely be emphasized that the vermiform appendix may, on account of its free mobility, be found in a great variety of positions within the abdominal cavity. If it has not become somewhere adherent, the position in which it is observed at necropsy is doubtless more or less a matter of accident, dependent on the conditions within the cavity. The range of positions in which it may be found under conditions of pathologic immobilization is remarkable, and covers nearly the entire peritoneal cavity. Besides its more frequent locations about the cecum and in and about the pelvis, it not rarely is found within a hernial pouch, either inguinal, femoral or "retroperitoneal" in one of the pericecal fossae.

Of the types of true hernia in which the appendix may be involved the inguinal occurs most frequently. In this variety the organ may be found in the inguinal canal or the scrotum either as a part of or, more rarely, as the only viscus in, the hernial content. The readily available figures which bear on these conditions indicate the occurrence of cecal and appendicular hernias as about 1.65 per cent. of all hernias. In Coley's[1] analysis of 2,200 cases of hernia in which operation was performed at the Hospital for Ruptured and Crippled, no femoral appendicular hernia was found, and but seventeen cases (or 0.77 per cent.) of inguinal hernia in which the appendix or appendix and cecum was present. In but ten of these instances was the appendix alone present in the hernial sac.

Descriptions of hernias in which the appendix is found seem largely confined to the occurrence of a displacement into an inguinal evagination of the peritoneum, which sac occurred either congenitally or appeared in later life as a result of those influences ordinarily responsible for hernia formation. The congenital type is apparently not very rare and may, it has been asserted, be diagnosed in infants and children through the presence of the cord-like appendix in a thin-walled sac. Only the very rare hernias of the fallopian tube or of the ureter have to be excluded.

Whether the condition be congenital or acquired, however, the appendix in such a case is found, together with the cecum if present, within a peritoneal sac which may be entirely patent or more or less obliterated by inflammatory exudate or adhesions. Under such circumstances the hernial content as a rule retains, either in whole or in part, its original serous covering. This form of hernia is therefore but a less common variation of the ordinary inguinal hernia.

---

* From the Laboratories of Pathology, Charity Hospital of Louisiana.

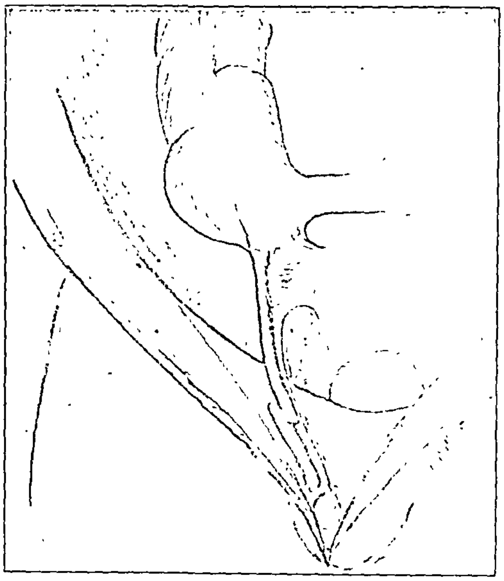
[1] Coley: Keen's Surgery, Philadelphia, 1912, iv, 78.

The primary causes of appendicular hernia are usually held to be the presence of an unobliterated pouch of the peritoneum, together with an abnormally movable cecum. The so-called "sliding" hernia of the cecum is a separate condition and is due to a more or less gradual retroperitoneal displacement of this structure.

Of evidently different causation, and of interest from both the anatomic and the embryologic points of view, is the following instance of what apparently was congenital implantation of the appendix in the inguinal canal, in which no trace of a hernial sac could be discovered:

A. J., a colored male infant of 6 months, was admitted Nov. 21, 1914. For two days he had suffered a very severe "cold" with marked intestinal disturbance. The condition improved under treatment, though the child did not nourish well, and malnutrition became serious. A history of scaling of the hands and feet was obtained, and a specific infantile iritis observed. December 18, the temperature rose to 103 F. and continued irregularly high. A double otitis media, due to *Staphylococcus aureus* infection, soon appeared. The child became progressively worse and died, Jan. 1, 1915, primarily on account of a terminal pneumonia.

At necropsy, beside confirmation of the clinical diagnosis, the following interesting condition of the appendix was observed: On routine inspection of the cecum for the purpose of determining the position and condition of the appendix, this organ seemed at first to be absent. From its usual point of origin, however, and continuous with the anterior longitudinal muscle band, was seen a somewhat flattened, thick, white cord of tissue which ran directly downward for a distance of 6 cm. to the internal abdominal ring, covered throughout by a fold of the peritoneum. External examination of the inguinal regions and scrotum revealed only bilateral enlarged lymph nodes. No evidence of sac or other abnormal subcutaneous structure could be detected. On reflection of the skin and fascia over the inguinal canal and scrotum, the appendiceal band was traced downward to end in a slightly bulbous tip, a short distance above the testicle.



Congenital inguinal implantation of appendix.

The fold of the peritoneum in the free border of which the appendix lay was a thin membrane which extended from the caput coli to the internal ring, a distance of 6 cm., and was attached to the border of the true pelvis. It was evidently an extension of the meso-appendix, and being analogous to the so-called appendiculo-ovarian ligament of Clado, the mesenteric fold which is found when the appendix extends to and is intimately connected with the ovary, it might possibly be termed an appendiculo-inguinal ligament. This membrane was, as has been stated, 6 cm. in length and was from 1.5 to 2 cm. in width, from the free border to its line of attachment. In its lower portion the vas deferens was plainly to be seen as a pale, small, cord-like structure, running backward in the membranous fold to its usual position on the pelvic wall. This duct lay internally to the appendix in the inguinal canal.

The presence or absence of any peritoneal sac or evagination was carefully observed during the dissection. From the abdominal cavity there was no sign of downward extension of the serosa. At the internal ring the peritoneum was reflected smoothly from the appendiculo-inguinal fold posteriorly, laterally to the right and anteriorly. In the canal there was neither remnant nor trace of the funicular process of the tunica vaginalis or of a subsequently formed peritoneal diverticulum. The adventitia of the appendix was of the normal, rather delicate connective tissue to be found in the subcutaneous tissues of infants. There was no evidence of scar tissue following inflammation. About the testicle the tunica vaginalis was normal.

That part of the appendix which lay in the inguinal canal and scrotum measured 5 cm. in length. It presented a sharp Z-shaped bend so that, when freed and straightened, this infraperitoneal portion measured 6.5 cm., making a total length of 12.5 cm. from the cecum to the tip of the appendix. The organ was large, rather flattened, and the lumen was patent very nearly to the end.

COMMENT

Had the condition described above been primarily due to the congenital presence or subsequent formation of a peritoneal sac, all trace of such a structure was lost, and nothing could be found that would indicate the obliterating process. No undue fibrosis was present, and aside from the kinking, there was no apparent interference with the development or nourishment of the appendix, such as might be expected following obliteration of a hernial sac.

Even when there is a peritoneal diverticulum for the reception of an abdominal viscus, the appendix cannot ordinarily be included in the hernia content unless the cecum is abnormally mobile or exceptionally low. In the present case the cecum was snugly suspended in its usual position, and a distance of 6 cm. intervened between it and the internal abdominal ring.

In a hernia of the appendix, this organ with its mesenteric band, with or without the cecum, drops or is forced into the sac. In any event it is, certainly at first, completely covered by peritoneum. The appendix herein described was, strictly speaking, retroperitoneal, being covered on but three sides by a fold of this membrane.

In view of these facts, it is held probable that the appendix was, during the descent of the testicle, in some manner included in the downward movement, and that it was drawn as a part of the spermatic cord through the internal abdominal ring, and was left without serous covering in the inguinal canal by the normal obliteration of the funicular portion of the tunica vaginalis. In this way may be explained its great length as compared to the age of the individual, its inguinal migration with a normally situated and supported cecum, its relation to the peritoneum and to the vas deferens, and its position and appearance in the inguinal canal.

Work in Heart Disease.—Work benefits equally the patient suffering from heart disease as it does the healthy individual. The only difficulty is that of knowing how to regulate the exercise, so that it shall be both effective and at the same time not an undue strain for the heart.—G. Norman Meachen, *Medical Press and Circular*, Nov. 11, 1914.

New Instruments and Suggestions

A MICROSCOPIC TEST FOR PASTEURIZED MILK (PRELIMINARY PAPER)

W. D. Frost, Ph.D., Dr.P.H., Madison, Wis.
Associate Professor of Agricultural Bacteriology, University of Wisconsin

METHODS FOR DETECTING HEATED MILK

Numerous methods have been proposed to test quickly and simply whether or not a given sample of milk has been heated. The methods suggested fall into three main groups:

1. Those based on the changes which the protein undergoes when milk is heated. These have not proved applicable in practice.

2. Those which depend on the presence of oxidizing enzymes in milk. Of these, Storch's test is generally regarded as most satisfactory. This, however, as is well known, can be used only on milk heated from 78 to 80 C. (172.4 to 176 F.). It cannot, therefore, be applied to milk heated to the temperatures employed for pasteurization in this country.

3. A microscopic test devised by myself and described in a paper by Frost and Ravenel in 1911 (A Microscopic Test for Heated Milk, *Proc. Am. Assn. Med. Milk Commissions*, May, 1911, p. 127).

Two features of this method interfered with its usefulness. One was the difficult technic and the other was the fact that safranin clotted the milk unless added with the greatest care. So far it has been possible to avoid this danger only by diluting the stain, and in this case the action of the dye is largely neutralized.

PRINCIPLES INVOLVED

The original idea that I had in mind was that by means of an *inter vitam* stain it would be possible to color the living leukócytes, as I assumed them to be in raw milk, in one way, and the dead cells, if such they are, in the heated milk, in another way. The technic was suggested by that employed in making opsonic index determinations. That it is possible, with proper experience, to differentiate pasteurized from raw milk by this means, is still my firm conviction.

Further study, however, has shown that it is possible greatly to simplify the technic, and at the same time emphasize the differential characters. It has also appeared that the principle of *inter vitam* staining need not be considered. The attempt can rather be made to stain the dead cells deeply and characteristically in the heated, and contrast these with the unstained or at most slightly tinged cells in the raw milk. It thus appears that the method here described may as well be considered a new method as a modification of the former or previously described method.

METHOD OF PERFORMING THE TEST

One part of a saturated aqueous solution of methylene blue is added to 5 parts of the milk to be tested. The dye should be added to the milk slowly to prevent the possibility of the stain coagulating the milk, for when this coagulation occurs the test is rendered unreliable. The method of adding the stain, which I have usually followed, is to put the milk in a small flask or beaker and add the dye slowly from a small pointed pipet while the milk is kept in motion by a rotary movement of the vessel.

The stain should be left in contact with the milk for from fifteen to thirty minutes, and then the sediment of the stained milk is precipitated in a centrifuge and spread on a glass slide. When the smear is dry it is ready for examination.

Probably the most convenient way of collecting the sediment is by means of the Stewart-Slack tubes, although it can be done quite readily in the tubes of a centrifuge such as are ordinarily used for collecting urinary sediments. In this case from 5 to 15 c.c. of the milk can be used, and this might be desirable in separated milk and cream. The 2 c.c. which the Stewart-Slack tubes hold, however, will ordinarily be found quite sufficient with whole milk.

The sediment is, perhaps, best spread on the glass slide by means of a glass spreader such as is frequently used in making blood smears. It is also quite possible to make the smear in the same way that is suggested by Slack for the direct enumeration of bacteria, that is, by means of rubbing the stopper over a definite area, such as 4 or 6 square centimeters.

THE STAIN

The methylene blue stain referred to above is made by adding about 7 gm. of Gruebler's dry dye to 100 c.c. of distilled water, allowing it to stand several hours with frequent shaking, and then filtering. Similar results can be obtained with saturated, aqueous solutions of safranin O soluble in water and Coget's Thionine and other stains, but so far the methylene blue has proved most satisfactory.

INTERPRETATION OF RESULTS

When the stains prepared by the method described above are examined under the microscope, the following pictures are seen:

1. *Raw Milk.*—The entire microscopic field is stained a light blue, the depth of the stain depending on the thickness of the film. In this blue background appear numerous clear areas, when viewed either with a low power (100 ×) or under an oil immersion objective. The smaller ones of these are fat globules, and the larger ones may be large fat globules, or clusters of the same, or more likely they are the leukocytes of the milk. These smears of the raw milk are quite uniformly stained, and the background is quite constantly more highly colored than any of the smaller objects in the fields. Under the high powers, oil immersion objective, the leukocytes are practically all colorless; but with some experience it is not difficult to learn to recognize them, and then it will be noted that the cells of the polymorphonuclear variety are irregular in outline and about 12 microns in diameter. The nuclear material, if differentiated at all, is not well defined. The mononuclear cells are always well stained, and are not considered in this test, and all descriptions of leukocytes apply only to the polymorphonuclear ones.

2. *Heated Milk.*—Smears made from heated milk do not have the background as deeply stained as the smears from raw milk, but in thick portions may be quite blue. The leukocytes are always more deeply stained than the background, and under the low powers of the microscope may be readily seen as dark blue areas in a lighter blue field. The background immediately surrounding these leukocytes frequently takes the stain deeply and shades off into the color of the background, thus forming a halo about the leukocytes. Under the oil immersion lens the leukocytes are readily visible; they are less irregular in outline than are those in the raw milk, that is, they are rounded up, or shrunken, and are only about 7 microns in diameter. The nuclei are distinctly stained. The amount of shrinking and the depth of stain vary somewhat with the degree of heat applied.

Even a cursory examination of the two smears shows a distinct and readily recognized difference between the smear from the heated milk and that from the raw milk.

The effect of heat on the leukocytes, so far as this test is concerned, is twofold. It alters the shape and size of the cells, and changes their staining reactions. The shape of the cell is probably gradually changed as the degree of heat increases, and the shrinking begins to appear at a lower temperature than that used for pasteurization; but the fixing of the nuclear material, which makes possible the absorption of the stain, seems to take place definitely at practically the same temperature as that fixed on as suitable for the pasteurization of milk, namely, at from 60 to 63 C. (140 to 145.4 F.).

REQUIREMENTS OF PASTEURIZED MILK

Properly pasteurized milks then, when examined by this method, should show the polymorphonuclear leukocytes more deeply stained than the background, rounded up and less than half the usual size of such cells, and should especially show the nuclei definitely stained. Controls of raw milk should probably always be run.

The primary causes of appendicular hernia are usually held to be the presence of an unobliterated pouch of the peritoneum, together with an abnormally movable cecum. The so-called "sliding" hernia of the cecum is a separate condition and is due to a more or less gradual retroperitoneal displacement of this structure.

Of evidently different causation, and of interest from both the anatomic and the embryologic points of view, is the following instance of what apparently was congenital implantation of the appendix in the inguinal canal, in which no trace of a hernial sac could be discovered:

A MICROSCOPIC TEST FOR PASTEURIZED MILK (PRELIMINARY PAPER)

W. D. Frost, Ph.D., Dr.P.H., Madison, Wis.
Associate Professor of Agricultural Bacteriology, University of Wisconsin

METHODS FOR DETECTING HEATED MILK

Numerous methods have been proposed to test quickly and simply whether or not a given sample of milk has been heated. The methods suggested fall into three main groups:

1. Those based on the changes which the protein undergoes when milk is heated. These have not proved applicable in practice.
2. Those which depend on the presence of oxidizing enzymes in milk. Of these, Storch's test is generally regarded as most satisfactory. This, however, as is well known, can be used only on milk heated from 78 to 80 C. (172.4 to 176 F.). It cannot, therefore, be applied to milk heated to the temperatures employed for pasteurization in this country.
3. A microscopic test devised by myself and described in a paper by Frost and Ravenel in 1911 (A Microscopic Test for Heated Milk, *Proc. Am. Assn. Med. Milk Commissions*, May, 1911, p. 127).

Two features of this method interfered with its usefulness. One was the difficult technic and the other was the fact that safranin clotted the milk unless added with the greatest care. So far it has been possible to avoid this danger only by diluting the stain, and in this case the action of the dye is largely neutralized.

PRINCIPLES INVOLVED

The original idea that I had in mind was that by means of an *inter vitam* stain it would be possible to color the living leukocytes, as I assumed them to be in raw milk, in one way, and the dead cells, if such they are, in the heated milk, in another way. The technic was suggested by that employed in making opsonic index determinations. That it is possible, with proper experience, to differentiate pasteurized from raw milk by this means, is still my firm conviction.

Further study, however, has shown that it is possible greatly to simplify the technic, and at the same time emphasize the differential characters. It has also appeared that the principle of *inter vitam* staining need not be considered. The attempt can rather be made to stain the dead cells deeply and characteristically in the heated, and contrast these with the unstained or at most slightly tinged cells in the raw milk. It thus appears that the method here described may as well be considered a new method as a modification of the former or previously described method.

METHOD OF PERFORMING THE TEST

One part of a saturated aqueous solution of methylene blue is added to 5 parts of the milk to be tested. The dye should be added to the milk slowly to prevent the possibility of the stain coagulating the milk, for when this coagulation occurs the test is rendered unreliable. The method of adding the stain, which I have usually followed, is to put the milk in a small flask or beaker and add the dye slowly from a small pointed pipet while the milk is kept in motion by a rotary movement of the vessel.

The stain should be left in contact with the milk for from fifteen to thirty minutes, and then the sediment of the stained milk is precipitated in a centrifuge and spread on a glass slide. When the smear is dry it is ready for examination.

Probably the most convenient way of collecting the sediment is by means of the Stewart-Slack tubes, although it can be done quite readily in the tubes of a centrifuge such as are ordinarily used for collecting urinary sediments. In this case from 5 to 15 c.c. of the milk can be used, and this might be desirable in separated milk and cream. The 2 c.c. which the Stewart-Slack tubes hold, however, will ordinarily be found quite sufficient with whole milk.

The sediment is, perhaps, best spread on the glass slide by means of a glass spreader such as is frequently used in making blood smears. It is also quite possible to make the smear in the same way that is suggested by Slack for the direct enumeration of bacteria, that is, by means of rubbing the stopper over a definite area, such as 4 or 6 square centimeters.

THE STAIN

The methylene blue stain referred to above is made by adding about 7 gm. of Gruebler's dry dye to 100 c.c. of distilled water, allowing it to stand several hours with frequent shaking, and then filtering. Similar results can be obtained with saturated, aqueous solutions of safranin O soluble in water and Coget's Thionine and other stains, but so far the methylene blue has proved most satisfactory.

INTERPRETATION OF RESULTS

When the stains prepared by the method described above are examined under the microscope, the following pictures are seen:

1. *Raw Milk.*—The entire microscopic field is stained a light blue, the depth of the stain depending on the thickness of the film. In this blue background appear numerous clear areas, when viewed either with a low power (100 ×) or under an oil immersion objective. The smaller ones of these are fat globules, and the larger ones may be large fat globules, or clusters of the same, or more likely they are the leukocytes of the milk. These smears of the raw milk are quite uniformly stained, and the background is quite constantly more highly colored than any of the smaller objects in the fields. Under the high powers, oil immersion objective, the leukocytes are practically all colorless; but with some experience it is not difficult to learn to recognize them, and then it will be noted that the cells of the polymorphonuclear variety are irregular in outline and about 12 microns in diameter. The nuclear material, if differentiated at all, is not well defined. The mononuclear cells are always well stained, and are not considered in this test, and all descriptions of leukocytes apply only to the polymorphonuclear ones.

2. *Heated Milk.*—Smears made from heated milk do not have the background as deeply stained as the smears from raw milk, but in thick portions may be quite blue. The leukocytes are always more deeply stained than the background, and under the low powers of the microscope may be readily seen as dark blue areas in a lighter blue field. The background immediately surrounding these leukocytes frequently takes the stain deeply and shades off into the color of the background, thus forming a halo about the leukocytes. Under the oil immersion lens the leukocytes are readily visible; they are less irregular in outline than are those in the raw milk, that is, they are rounded up, or shrunken, and are only about 7 microns in diameter. The nuclei are distinctly stained. The amount of shrinking and the depth of stain vary somewhat with the degree of heat applied.

Even a cursory examination of the two smears shows a distinct and readily recognized difference between the smear from the heated milk and that from the raw milk.

The effect of heat on the leukocytes, so far as this test is concerned, is twofold. It alters the shape and size of the cells, and changes their staining reactions. The shape of the cell is probably gradually changed as the degree of heat increases, and the shrinking begins to appear at a lower temperature than that used for pasteurization; but the fixing of the nuclear material, which makes possible the absorption of the stain, seems to take place definitely at practically the same temperature as that fixed on as suitable for the pasteurization of milk, namely, at from 60 to 63 C. (140 to 145.4 F.).

REQUIREMENTS OF PASTEURIZED MILK

Properly pasteurized milks then, when examined by this method, should show the polymorphonuclear leukocytes more deeply stained than the background, rounded up and less than half the usual size of such cells, and should especially show the nuclei definitely stained. Controls of raw milk should probably always be run.

RESULTS OF USE

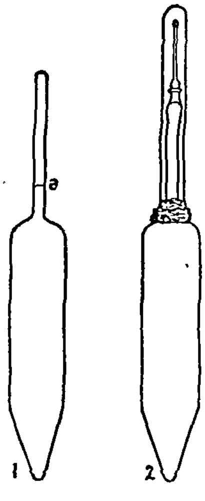
This method has been tested on many samples experimentally pasteurized in the laboratory and on several samples of commercially pasteurized milks. In a considerable number of cases, myself and two others, one with considerable practice and the other with practically none, have found it readily possible to differentiate the properly pasteurized from the raw samples. I feel sure that any one who will take the necessary time to familiarize himself with the test will be able to separate milk heated to 60 C. and above from raw milk, with the same ease and certainty that the bacteriologist now makes a laboratory diagnosis of diphtheria or rabies, and in little more time than is required to stain and examine for tubercle bacilli in sputum.

Part of the work done on this test was performed while I was working in the Laboratories of Preventive Medicine and Hygiene at the Harvard Medical School, and I desire to thank Dr. M. J. Rosenau for many courtesies extended. I also wish to thank my assistant, Miss V. A. Armstrong, for constant help.

THE VACUUM TUBE OF KEIDEL, AS APPLIED TO BLOOD-CULTURE WORK *

C. C. W. Judd, M.D., and Charles E. Simon, M.D.,
Baltimore

While blood-culture has long occupied an important position as a diagnostic method in all modern hospital laboratories, it has almost completely failed to popularize itself among general practitioners. The reasons for this are self evident. Very few general practitioners probably have private laboratory facilities at their disposal which would enable them to carry to the sick-bed all the paraphernalia which blood-culture, as hitherto practiced, demands. Moreover, a single negative result is rarely of value, while repeated examinations would frequently not be tolerated by the patient, to whom a vein puncture with a large needle is by no means an indifferent procedure. To meet these objections to an otherwise most valuable method of investigation, it occurred to us that the entire procedure might be very much simplified by the use of large vacuum tubes analogous to those which were introduced by Keidel for the collection of blood for Wassermann work, *the culture medium being placed in the tubes.* Preliminary experiments which Dr. G. H. White carried out during the fall of 1912 and the following winter showed conclusively that the method is thoroughly practical and trustworthy, and since then all blood-culture work both at the laboratory of the College of Physicians and Surgeons and in Dr. Simon's private laboratory have been conducted on this basis.



Tube for blood-culture work; one quarter natural size: 1, open tube; 2, parts assembled; *a*, point at which the tube is sealed after exhaustion.

The tubes which we are now using are manufactured by the Steele Glass Company of Philadelphia. They are illustrated in the accompanying diagram. Their capacity is approximately 50 c.c. From 15 to 25 c.c. of glucose bouillon containing 1.5 per cent. of sodium citrate (to prevent coagulation) are placed in each tube. This is most conveniently accomplished by drawing out the neck at the mark *a* to a comparatively fine caliber, without seriously weakening the glass, when each tube is connected with a suction pump and a vacuum established. The connecting rubber tube which leads to the pump is clamped, slipped off and plunged into the culture medium, when this is again connected with the suction pump, the desired degree of vacuum established and the neck sealed at *a* where it was previously drawn out. The tubes are then provided with a stout rubber cuff, armed with a No. 24 needle which, in turn, is supplied with a stylet. Thin tubing is unsuitable, as it will collapse when suction is established. The needle which we use is a trifle larger than that going with the Keidel tube, but still sufficiently small as not to cause any inconvenience to the patient. Needle and cuff are guarded with an outer glass tube, as usual, and the entire apparatus is sterilized—best by heating in the autoclave for five minutes after the pressure has reached 20 pounds. Thus prepared, the tubes may be stored, and are then ready for use at any time.

When a blood-culture is to be made, the patient's arm at the bend of the elbow is cleansed with soap and water, and alcohol and ether in the usual manner; a constricting band is placed around the upper arm, and any prominent vein punctured that may present itself. After this has been done, the sealed end within the rubber cuff is broken off, when approximately 5 c.c. of blood are allowed to enter. The constricting band around the arm is removed as soon as the blood begins to flow. The needle is then quickly withdrawn, the guard tube replaced, and the reassembled outfit carried to the laboratory. If this is at a distance, necessitating the mailing of the tube, the rubber cuff is removed under aseptic precautions, and the broken end of the collecting tube sealed in a Bunsen or alcohol flame. Otherwise this is not necessary and the entire apparatus may be placed in the incubator, as it is.

After twenty-four hours the corpuscles will have settled to the bottom, while the supernatant fluid becomes perfectly clear and remains so, if no growth has occurred. If positive, a turbidity results which develops either within twenty-four hours, or later, and varies in appearance with the character of the organism. Then, and not before, are the contents of the tube examined in the smear, and, if desired, by subcultures, though the latter are not always necessary.

The results which we have obtained with this procedure have been most gratifying. The isolation of all the common organisms which may be found in the blood (including the various types of streptococci and pneumococci) is effected without difficulty, and we feel that blood-culture with this method is now a sufficiently simple matter to be within the reach of any physician who is provided with even very modest laboratory facilities. The inconvenience caused the patient is, moreover, so slight that no objection is likely to be raised to even frequent repetitions of the puncture.

While the procedure, as above described, is one that will usually be adopted for the isolation of aerobic organisms, the same method may be employed if anaerobes are to be cultured. In that event, a vacuum is again established after inoculation of the culture medium, and the tube sealed off as in the beginning. Or, as an extra precaution, the medium may be layered with liquid paraffin before sterilization.

We may mention that we are using corresponding tubes for the collection of blood for various other purposes. For coagulation-time determinations, according to Howell's method, a smaller model is employed, charged with oxalate solution and graduated accordingly. Plain collecting tubes of large caliber are used for the purpose of obtaining blood for the Abderhalden and Fauser reactions, for the preparation of salvarsanized serum, for the collection of antiserums in animals, etc.

The underlying principle in all, of course, is the vacuum method of Keidel, to whom we cheerfully give all credit for its extension to other purposes also than the collection of blood for the Wassermann reaction.

Observation and Theory.—It is not true that observations compel any one theory. In fact, as Poincaré has shown, there is an infinite number of explanations of any finite set of facts. From among this enormous totality we must select the explanation which is most satisfying for us from considerations of convenience or from the demands of the esthetic sense. This is actually what we always do. It should be done consciously.—R. D. Carmichael, *Science.*

AN IMPROVED ETHER MASK

William L. Wolfson, M.D., Brooklyn
Assistant Visiting Gynecologist, Jewish Hospital

Innumerable methods for the oral administration of ether as an anesthetic have been devised. The simplest is a piece of cloth, of varied thickness, or texture, placed over the mouth and nostrils; the most complicated are those apparatus of complex and expensive manufacture, with special heaters for the warming of ether vapor, intrathoracic pressure regulators, etc. The latter appliances have no value to the ordinary practitioner, whose anesthetic needs are confined to his office or his patient's home, but they have a definite, important and necessary use at hospitals for prolonged, difficult or special operations.

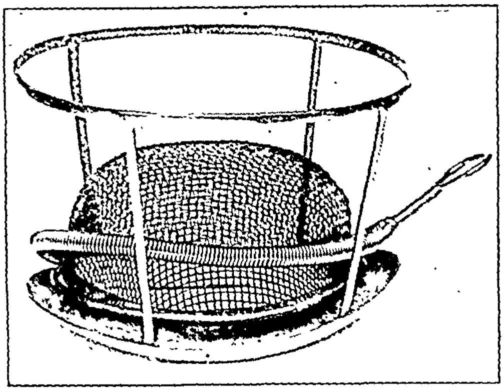

Fig. 1.—Mask, as it appears without the gauze for ether and canton flannel bag.

Of the simple devices for administering ether in common use, the Ochsner-Mayo, Yankauer and Ferguson masks have deservedly attained the greatest popularity. With all of these masks, ether is given by the open drop method.

There is little doubt that of these the Ferguson type of mask is the most efficient. Made of wire, it has an oval base to fit around the nose and mouth; arching across this base are several wire supports for gauze, on which the ether is poured. The gauze is held in position by another oval wire that presses it firmly against the base. Four wire columns, two on each side, arise from the base of the mask. They are directed upward and outward, and are surmounted on top by a circular wire. A specially made bag of Canton flannel fits around the four columns and the top wire, converting this enclosure into a semiclosed chamber, the opening being above, the size of which may be regulated with a purse string. It is through this opening above that the ether is dropped on the gauze directly below.

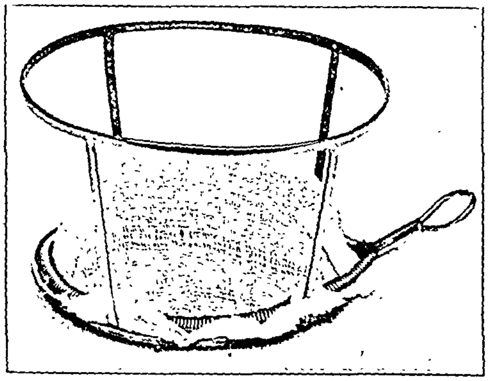

Fig. 2.—Shows the gauze for ether snapped firmly into position.

The advantages possessed by this mask are: 1. It provides a semiclosed chamber into which ether is permitted to vaporize and become warmed. 2. An appreciable degree of rebreathing takes place. 3. The amount of air accessible to the patient is easily regulated by the purse-string opening.

What merits the Ferguson mask possesses are greatly offset by a number of grave disadvantages. It was assumed that, the oval base being made of flexible wire, the shape of the mask could be bent to each individual face. After a few such attempts, I have been disappointed to find the mask greatly distorted, the gauze-locking device uncertain and the mask entirely unmanageable.

To eliminate a number of grave disadvantages that the Ferguson mask possesses, and at the same time to combine its excellent features with those of the Yankauer mask, I devised a new mask, made up for me by Sands & Levy of Buffalo.

As a base I have used the rigid Yankauer mask. The shape of this mask lends itself to almost every face. Rarely is it necessary to wrap a towel about it, to withhold an excessive amount of air accessible to the patient. Its oval spiral spring arrangement for the rapid and firm fixation of gauze in place is excellent (Fig. 1). On the sides of this mask are erected four columns, two on either side. These columns are made up of spring band German silver, ⅜ inch wide. They are surmounted on top by a circular band of the same material (Fig. 2). This insures an air chamber of permanency and stability.

As completed, with the Canton-bag covering (Fig. 3), this mask affords every advantage of both the Ferguson and Yankauer masks, and omits a number of their serious disadvantages. Its advantages are:

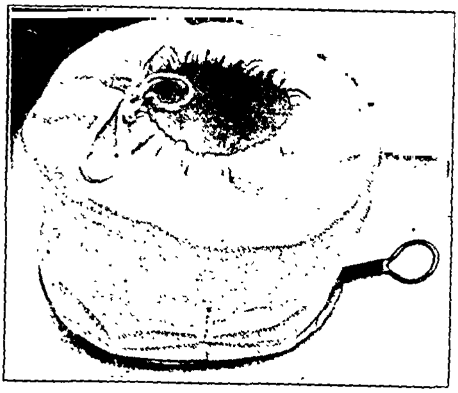

Fig. 3.—Mask as completed, with the canton flannel bag surrounding it; opening above regulated by a purse string.

1. Durability, rigidity and permanent shape. 2. The easy, precise and firm fixation of gauze. 3. Possession of an air chamber for the vaporization of ether. 4. The regulation of air accessible to the patient.

I am anxious to express my indebtedness to Dr. I. D. Kruskal, visiting anesthetist to the Jewish Hospital, under whose direction this mask has been in use for more than a year.

3003 Clarendon Road.

AN ELECTRIC HEATER FOR STAINING THE TUBERCLE BACILLUS

Carl L. A. Schmidt, Berkeley, Cal.
Chemist and Bacteriologist, Health Department Laboratory

The method of staining the tubercle bacillus by holding the slide over a small flame to steam is both slow and tedious, especially when a number of slides are to be stained. To overcome this, I have devised a simple electric heater which can be made in any laboratory, and whereby a number of slides can be stained at the same time.

The heater consists essentially of a heating unit mounted on a galvanized iron test-tube support (E. & A. No. 6694).

To the under part of the wire frame is fastened a thin piece of sheet iron to secure even distribution of heat and to prevent liquids being spilled on the heating element. About a quarter inch below this is the heating unit. This was made by wrapping about 30 feet of Nichrome ribbon wire 1/32 inch wide around a rectangular sheet of mica of nearly the same dimensions as the support. This is insulated on both top and bottom by similar sheets of mica and the whole mounted on a heavy piece of asbestos board which is fastened to the corners of the support. The wire terminals lead to binding posts which are fastened to the asbestos board. The resistance of the heating circuit is about 80 ohms which requires, on a 110 volt direct current circuit, about 1.4 amperes. This will produce enough heat to steam the slides without danger of burning should the stain evaporate. About ten slides can be stained at once.

Nichrome wire is well adapted for use in heating units on account of its high specific resistance, non-corrosiveness and high melting point. It can be bought in either wire or ribbon, the latter being the more convenient for making a heating unit. The wire is made in various widths and thicknesses.

The heater here described has been used in this laboratory for some time with excellent satisfaction.

A SIMPLE APPARATUS FOR THE ADMINISTRATION OF CHLOROFORM AND ETHER BY THE VAPOR METHOD

O. M. Layton, M.D., Fond du Lac, Wis.

The administration of ether and chloroform by the vapor method has certain advantages over the older methods, of which the most obvious are lessened danger of overdose, greater freedom from bronchial irritations, and its ready adaptability to throat work.

Junker's chloroform inhaler has been on the market for a number of years, and can be bought for about nine dollars, while there are a number of different apparatus for the administration of ether vapor to be had at prices varying from twelve to about two hundred dollars.

I have recently devised a simple and compact little apparatus for the administration of both drugs by the vapor method.

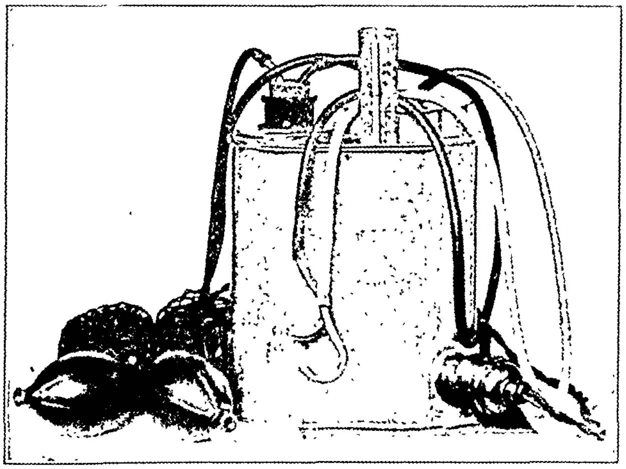

Fig. 1.—Apparatus for administration of chloroform and ether anesthesia.

This apparatus has proved very satisfactory in my hands, and can be constructed by any tinsmith at a cost which need not exceed five dollars, including the cost of bulbs and tubing.

The apparatus consists of an oval tin container 7 inches in length by 7½ in height; a removable top, to the under side of which are soldered two tin tubes 5 inches in length and 2½ and 3½ inches in diameter, perforated at the bottom and open at the top for the reception of the 4 and 8 ounce bottles. A circular tin cover with a central opening passes over the necks of the bottles, dropping to the shoulders of these.

The base for an electric light bulb is soldered in the side of the apparatus near the bottom and fitted with a 15 watt bulb. An ordinary thermometer is secured between the bottle holders.

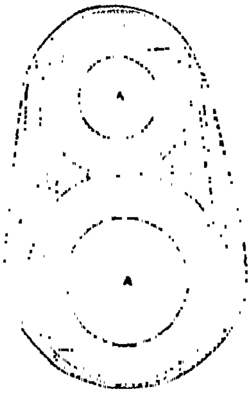

Fig. 2.—Top of apparatus: *A, A*, openings which pass over the necks of the bottles; *B, B*, circular tin cover; *C, C*, removable tin top.

The tubes may be of 3/16 inch brass or glass, and are bent at convenient angles. The inlet tubes to which the rubber bulbs are attached extend to the bottom of the bottles; the outlet tubes just through the corks.

The curved tubes at the end of the rubber delivery tubes are hooked inside of the dome of an ordinary wire inhaler which has been covered with a dozen layers of surgical gauze. In throat work, whichever tube is used may be carried inside the angle of the mouth, or the rubber tubing connected to any of the mouth gags constructed for use with the vapor method.

When in use, the temperature of the interior of the apparatus should be maintained at 85 F.; this may be accomplished with warm water if electricity is not available.

Compression of the bulbs should be timed so as to deliver the vapor to the patient at the beginning of each inspiration.

The strength of ether vapor as delivered I have found to be about right for the average patient for maintenance of satisfactory anesthesia. If for any reason one does not wish to anesthetize his patient with chloroform, he may use the ether drop method and change to the ether vapor method as soon as the patient is properly anesthetized. I have now tried this out in about 300 anesthesias within the past year, the work having been done in St. Agnes Hospital, in the surgical service of J. P. Connell, M.D., to whom I am indebted for the opportunity, as well as for many kindly suggestions.

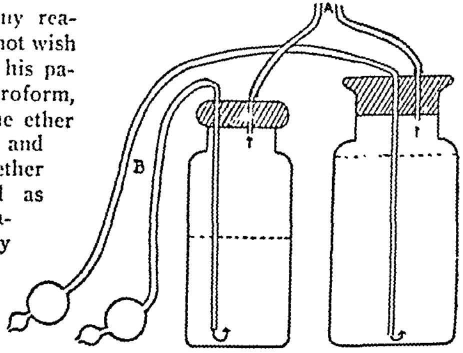

Fig. 3.—Bottles for ether and chloroform: *A*, delivery tubes; *B*, cautery bulbs and tubes.

Sleeping Sickness in Portuguese West Africa.—Consul-General Henry A. McBride, stationed at Boma, Belgian Kongo, West Africa, has made a trip through Angola, a Portuguese colony in West Africa, twice as large as the state of California. He says that in the district of Loanda and east as far as the Kwango River there are many localities in which sleeping sickness is prevalent. The principal region is along the Kuanza River where the tsetse fly abounds. In this district the sleeping sickness has almost caused the disappearance of a population once numerous and flourishing. The mortality from the disease so seriously interfered with the supply of labor on farms and plantations that in 1902 the Portuguese government sent a commission of the most eminent bacteriologists in Portugal to investigate it, with the result that measures were adopted against it, and its prevalence is far less than it was ten years ago. It is proposed to build a large sleeping sickness hospital at Ambaca. Consul McBride also says that several severe epidemics of smallpox have occurred in various parts of the colony.

IX

B. DEPRESSANTS: 6. HYDROCARBON NARCOTICS

The terms "soporific," "hypnotic" and "narcotic" are sometimes used without a clear understanding of their meaning. "Soporific" (from the Latin *sopor*, sleep) and "hypnotic" (from the Greek ὕπνος, sleep) may be considered as having an identical significance; they are applied to drugs that induce sleep closely simulating natural sleep. The term "narcotic," from νάρκη, stupor) is applied to those drugs which in moderate doses produce a more profound depression of the higher centers than occurs in natural sleep.

The following will serve to distinguish between them: Moderate doses of hydrated chloral induce sleep, during which sudden noises are perceived and their character recognized, while the patient is awakened to a normal condition, showing that the centers concerned with the perception of sound are almost as active as normally. Larger doses of hydrated chloral induce narcosis, during which the loudest noises do not awaken the patient nor can evidences of consciousness be elicited by any ordinary means, such as shaking or pinching, the perception of pain being abolished, of course.

The stage of hypnosis passes gradually into that of narcosis, and while there is no sharp distinction between them, we use the terms "soporific" and "hypnotic" for such drugs or doses as induce the lighter stage of sleep, and "narcotic" for those drugs or doses which abolish the perception of pain and induce profound depression of the higher centers.

The hydrocarbon narcotics may be subdivided for convenience of consideration into the following groups: alcohol, chloroform and ether; hydrated chloral and other hypnotics. They have very similar actions in general, differing mainly in the rapidity with which their actions are induced and their duration; hence it will be convenient to discuss the subject of narcosis briefly, even though many of the drugs of this group are never actually used therapeutically for their narcotic effects.

Many theories have been advanced to explain the action of narcotics, and while none of these is satisfactory, there is one which has gained acceptance more widely than the others. Hans Meyer and Overton advanced theories independently which are similar in many respects, and which are usually spoken of as the theory of Meyer and Overton. They believe that the narcotic activity of different agents is dependent on their relative solubility in lipoids (lecithin-albumin compounds) and in water or serum, and that this activity does not within wide limits depend on the solubility in water or serum alone.

Meyer determined the relative solubilities of various agents in water and fats, or lipoids, designating this relationship as the "coefficient of distribution." He found that those having a relatively great solubility in lipoids are more actively narcotic than those having a relatively greater solubility in water. He believes that chemically indifferent substances enter the cells of the central nervous system by reason of their solubility in the cell envelope, and that their narcotic activity then depends on their possessing molecular groups which affect the internal relations of cell compounds.

The chemically indifferent narcotic compounds exert their actions on all forms of cells which they penetrate, but not all substances having a relatively high degree of solubility in lipoids are actively narcotic, benzene, for example, being nearly devoid of this action.

Baglioni has suggested that anesthesia results from the withdrawal of oxygen from certain compounds in the central nervous system, and it is well known that narcosis results when the inspired air is deprived of oxygen. Other theories do not require mention here.

ALCOHOL—(A)

There are two diametrically opposed theories which are frequently urged to account for the earlier actions of alcohol on the central nervous system. Binz believed that alcohol stimulates the central nervous system, while Schmiedeberg holds that the action is wholly depressant and that such increased functioning as follows the use of alcohol results from the abolition of inhibition on the centers which normally exercise control over those which then show apparent stimulation.

The weight of opinion is in favor of the view that alcohol stimulates certain parts of the nervous system, the stimulation being brief, usually lasting about half an hour. Jacobi found that the motor areas of the cortex became hyperexcitable and that smaller differences in weight could be appreciated after alcohol, while even the largest doses did not cause paralysis of the motor areas.

There is no clear evidence that alcohol increases the capacity for performing the highest type of mental work, such as clear judgment and the exercise of sound logic require, but the evidence is overwhelming that the capacity for such effort is distinctly lessened, though rapid association of ideas and such feats as rhyming may be facilitated. Such stimulation as alcohol induces is soon followed by depression. The effects of the stage of stimulation are so well known that they do not require detailed discussion here. The flushed face, the flashing eye, the ready wit, the good humor are sufficiently familiar to all.

Large amounts of alcohol lead to narcosis, which will be discussed when chloroform and ether are considered.

The respiration is greatly accelerated during the stage of excitement, just as it is during excitement from other causes, but the therapeutic use of alcohol results in a slightly increased respiration even during sleep. This is frequently attributed to a direct action on the centers in the medulla, but it is not known whether the action is direct or a reflex from the peripheral irritation. At any rate, respiratory depression does not occur unless the dose is large.

The vessels of the skin dilate after moderate doses of alcohol, and this dilatation is sometimes accompanied by a constriction of the splanchnic vessels which is sufficient to increase the blood-pressure slightly; but the changes in blood-pressure are only slight unless large doses have been administered, in which case there is a marked vasodilatation and fall in the pressure. It is not profitable to enter into a discussion here of the seat of this action, because the question is still unsettled.

---

* This is the ninth of a series of articles on useful drugs—on practical pharmacology for the general practitioner. As soon as completed, these articles, elaborated by additional subjects, will be published in book form.

The vagus center and that concerned with the emesis are probably not affected directly.

The heart-rate is not changed after therapeutic doses of alcohol, though the contraction may be slightly stronger, and it has been suggested that this is due to the supplying of energy directly by the alcohol. This, however, does not seem to be a satisfactory explanation. The behavior of the blood-pressure is inconstant, and it is probably of less importance than is the distribution of the blood.

Alcohol acts on the muscles directly and indirectly through the central nervous system. The direct actions are exerted in opposite directions. The immediate effect on muscular effort is to diminish the efficiency of the individual contractions, and the remote, to delay the onset of fatigue. Under its influence the muscle contracts less perfectly from the start but continues at this slightly lower level for a longer time, with the result that more work is performed before it becomes exhausted. It must be understood that this action is available only occasionally, for the habitual use of alcohol interferes with muscular efficiency, as it does with nearly all of the functions of the body.

The reason for the delay in the onset of fatigue when alcohol is applied to the muscle directly is that the alcohol is oxidized to carbon dioxid and water, which are immediately removed, while the oxidation furnishes muscular energy, and the fatigue products accumulate more slowly than normally.

This action is probably negligible when alcohol is taken by the mouth, and the central action is then responsible for the increased capacity for muscular effort. It does this by facilitating the excitation of the motor areas and by lessening the perception of fatigue. Alcohol may therefore prove useful in an emergency, when it becomes necessary to continue physical exertion beyond the time when excessive fatigue would demand rest. The factors involved in increased voluntary muscular effort would not affect the action of the heart, and it is difficult to explain its improving the cardiac action on the basis of any direct action, or of the lessened perception of fatigue; hence we must suppose that any improvement in the condition of the heart which it induces must be secondary to circulatory changes.

The association of parental alcoholism and degeneration or pathologic conditions in the offspring have long been recognized. It is known that epilepsy is more frequent in the offspring of alcoholics than of abstainers; a recent report, moreover, calls attention to the fact that alcoholic intoxication in the father at the time of impregnation may result in an epileptic child even when there is but the single indulgence in alcohol.

The high tax on ethyl alcohol has led to the abuse of methyl alcohol, which should not be used internally or externally on the body. A great number of fatal cases of poisoning or blindness have resulted from its use.

It is often claimed by the manufacturers of wood alcohol that blindness following its use is due to impurities present, but the purest wood alcohol obtainable causes blindness, and this action is explained by the retention of the methyl alcohol in the central nervous system and its slow oxidation to formic acid, which acts on the retina, causing degeneration.

Alcohol is absorbed rapidly from the gastro-intestinal canal and it also favors the absorption of other substances, probably through its mildly irritant action on the mucous membrane.

Alcohol is eliminated fairly rapidly when small amounts are taken, the habitual user burning it faster than the non-habituated. It has been found that only about 2 per cent. of a dose of 70 gm. (2½ ounces) escaped oxidation when taken during rest, in which extremely small amounts escaped from the lungs. Ten times as much may escape oxidation and be eliminated by the lungs when alcohol is taken during exercise.

Gastric digestion is not materially affected by moderate amounts of beer and wines of low alcoholic content, and they may even promote digestion; but brandy and whisky, containing about 50 per cent. of alcohol, interrupt digestion when they are taken in sufficient amount, and digestion is not resumed until the concentration of the alcohol is reduced sufficiently through absorption or dilution with the gastric contents.

Alcohol is antiseptic, absolute alcohol being much less active than that of 70 per cent. strength. This is probably explained by the fact that the stronger alcohol dehydrates the bacteria, increasing their resistance.

The continued moderate use of beer and other beverages of low alcoholic content commonly results in a gain of weight, due mainly to an increase in fat. Alcohol is also capable of sparing protein in those who have become habituated to its use, but not in those who use it only occasionally, or for a short time.

The dilatation of the vessels of the skin causes a sensation of warmth, because the increased blood-supply increases its temperature. This leads to a greater loss of heat than normally, and the body temperature may actually fall, even while one feels warmer, because the increased heat loss is not compensated for by increased heat formation. For this reason, the practice of taking alcohol before going out in extremely cold weather is dangerous, and severe exposure has often proved fatal under such circumstances. It is more rational to take alcohol when one returns to a warm room after having suffered from exposure to the cold, for then sensation of warmth acts as a stimulant, while the warmth of the room prevents further loss of heat.

The treatment of chronic alcoholism cannot be discussed here in detail. Attention was recently called to the often-observed fact that those who are fond of alcohol are not usually fond of sugar, while those who like sugar care little for alcohol; the theory was advanced that chronic alcoholism results from a disturbance of physicochemical balance, which may be corrected by diminishing the supply of alcohol and increasing that of sugar in the diet.

Common experience shows that individuals differ widely in their response to alcohol. The average fatal dose for a non-habituated adult is probably the equivalent of about 100 to 150 c.c. (3 to 5 fluidounces) when taken in fairly concentrated form, such as brandy or whisky. The more dilute forms, such as wine and beer, are not correspondingly active, because excretion then more nearly keeps pace with absorption. On the other hand, the more concentrated alcoholic beverages are more irritant to the stomach, and cause protective emesis more commonly than the weaker ones.

The first stage of alcoholism may be disregarded here, as it does not usually call for therapeutic treatment and is of minor toxicologic interest, but severe acute alcoholism, while rarely fatal, is extremely common and often demands treatment.

The more common type of acute alcoholism seen in habitués is different in several essentials from that seen in the non-habituated, and will be discussed first.

The common drunkard usually falls asleep under the influence of alcohol and will so remain if undisturbed, but when awakened he is prone to show excitement and extreme pugnacity that is difficult to control. The practice prevailing in some of the metropolitan hospitals in dealing with such patients is as follows: The stomach is washed, not so much to remove alcohol, which has usually been absorbed, as to remove undigested food and relieve nausea and vomiting, and to secure the retention of medicine. A dose of magnesium sulphate (half a pint or more of 10 per cent. solution) is then passed through the tube and allowed to remain in the stomach with the object of causing active purgation. This is followed by the administration of large doses of paraldehyd—three or four teaspoonfuls every half hour until excitement is controlled. This may seem contra-indicated in alcoholic intoxication, in view of the similarity of action of the two, but it is said to act extremely well in controlling the delirium of inebriates. Of course it is not used when deep narcosis results from the alcohol, which is rare in these cases.

When extremely muscular inebriates cannot be controlled sufficiently during the maniacal stage to permit of washing the stomach, a hypodermic injection of apomorphin, 0.008 gm. (⅛ grain), suffices to cause emesis and promptly reduce the patient to docility.

Severe alcoholic intoxication in the non-habituated usually causes more profound depression, which may succeed the first stage gradually, or may develop suddenly, causing death within a few minutes. During the narcotic stage there is active dilatation of the vessels in the skin, the face becoming scarlet, but soon there is a great fall of blood-pressure, due to the dilatation of the splanchnic vessels, and the skin of the trunk and extremities becomes cool and clammy, the respiration becomes stertorous, the pulse feeble. Emesis may occur at any time before narcosis develops, owing to the gastric irritation. When profound narcosis begins emesis stops, but it may recur as the narcosis passes away. The urine and feces are often evacuated involuntarily; with the failure of respiration the skin becomes cyanotic, as in asphyxia from any cause. The odor of alcohol on the breath is characteristic.

Chronic inebriates may of course present the stage of profound narcosis when the amount of alcohol taken is excessive, but this is unusual. The patient generally recovers after sleeping a variable length of time, but Kobert states that recovery seldom takes place after coma lasting more than thirteen hours. Death occurs rarely from rapid failure of the respiratory center, or from apoplexy; edema of the lungs may result in death after some days. Cardiac failure or apoplexy may cause sudden death after the patient is apparently on the road to recovery, or this may result after some days from pneumonia or encephalitis. The latter is of interest in view of the suggestion that the headache which commonly follows a drinking bout may be due to pressure of cerebrospinal fluid on the brain due to increased secretion resulting from alcohol.

When a patient is seen after taking a dangerous dose of alcohol, the stomach should be emptied by the stomach-tube as promptly as possible, but, as previously suggested, this does not serve to remove much of the alcohol unless it is done immediately after the administration of the alcohol. If a dangerous amount of alcohol has been swallowed, the further treatment must be largely symptomatic—cold applications to the head, and warm applications to other parts of the body to prevent cooling. It has been suggested that venesection might be considered, but that would seem to be a council of desperation. It would seem to be more logical to inject as much as a liter (1 quart) of 2 per cent. solution of sodium sulphate intravenously in desperate cases, in order to dilute the alcohol which continues to circulate in the blood, and possibly to hasten elimination, though little benefit is to be expected probably.

Caffein is antagonistic to moderate amounts of alcohol, but its value in excessive depression is problematic. It should be administered intramuscularly (not intravenously) with caution and stopped if it fails to cause prompt, even though slight, improvement. Artificial respiration will be required if respiratory failure threatens.

Should the more threatening symptoms subside, the physician will be called on to treat the gastric disturbances and the headache which follow the narcotic stage. These demand the usual gastric sedatives, and caffein and potassium bromid for the headaches.

The following may be found of advantage in such cases:

Bismuth subnitrate.........10 gm. or 2½ drams.

Make five powders and give one every three hours until all are taken.

The addition of an alkali is preferred by some and may be directed as follows:

Bismuth subnitrate	10 gm. or 2½ drams.
Sodium bicarbonate	5 gm. or 1¼ drams.

Mix and divide into five powders. Give one three times a day.

For the more aggravated case of alcoholic gastritis a moderate dose of cocain may be found advantageous.

Cocain hydrochlorid	0.05 gm.	or 1	grain
Bismuth subnitrate	10.00 gm.	or 2½	drams
Mucilage of acacia	20.00 c.c.	or 5	fluidrams
Syrup	20.00 c.c.	or 5	fluidrams
Water to make	100.00 c.c.	or 3	fluidounces

Mix and direct that one tablespoonful be given and the dose repeated in two hours if necessary.

Caffein may be administered with the bismuth or preferably separately in the form of capsules either as caffein, citrated caffein, or caffein sodiosalicylate, 0.3 gm. (5 grains) in each capsule.

Potassium or sodium bromid as a sedative is best administered in the form of simple aqueous solution, 2 gm. or 30 grains in about 20 c.c. of water. The bromids are usually borne best when administered with simple carbonated water.

THERAPEUTIC USES

Few drugs have been used more extensively than alcohol, and few continue to be the subject of more heated debate. Cabot remarked that there are two camps opposed to each other concerning the actions of alcohol. In the one, those who believe alcohol to be useful in therapeutics are unable to give more than vague impressions that patients improve with its use, or *to state wherein the improvement is shown.* On the other hand, the opponents of the use of alcohol usually cite old experiments on animals in which enormous amounts were used, or the results obtained with soldiers, typesetters and others who were undergoing feats of endurance. Cabot found the action of alcohol to be practically nil with respect to the blood-pressure in 1,105 measurements on forty-one patients suffering with typhoid fever; nor could he observe any constant effect after therapeutic doses of alcohol with respect to temperature, pulse-rate, respiration rate, appetite, sleep, delirium or renal or cutaneous secretion in 2,160 observations on 309 patients in a variety of conditions. Cabot does not deny, however, that alcohol may have well-defined uses as a vasodilator and hypnotic.

One reason for the diversity of opinion concerning the therapeutic value of alcohol is that it is often used for its psychic effects, to buoy up the spirits of the patient and engender hopefulness and courage—conditions which physicians impart to their patients in such variable degrees by their manner and self-confidence.

It is obvious that alcohol effects changes in the distribution of the blood. In order to do this it must increase the blood-supply to some regions of the body and diminish that to others, and it is hardly conceivable that such changes should not prove beneficial in some cases and harmful in others. The selection of those cases in which the changes will be desirable, while avoiding the use of alcohol in those in which it will prove deleterious, will tax the knowledge, experience and patience of the practitioner.

It is often stated that alcohol improves the circulation in shock. One eminent pharmacologist calls attention to the dilatation of the vessels of the skin and explains the improvement sometimes seen after its use when the heart is beating feebly, as due to the lessened resistance to the contraction of the heart which this dilatation affords, thereby permitting recuperation. Another equally eminent authority cites this dilatation of the vessels of the skin as evidence that the splanchnic vessels are simultaneously constricted, according to the usual physiologic rule of compensating action between the peripheral and splanchnic vessels, and states that the improvement in the heart results from the increased *blood-pressure, which of* course increases the resistance against which the heart must contract, but which also affords a better blood-supply to the heart itself.

Alcohol may cause increased resistance at one time and decreased resistance at another, and while it is impossible to foresee which will follow in a given case, improvement in the condition of the heart may follow a rise of pressure when this was previously low, or a *fall in pressure provided it was not previously too low.*

When the heart is suffering with the effort to contract against high aortic resistance, the effect of the changes in circulation induced by the administration of alcohol will depend on the relative changes in the coronary and in the general circulation. If the blood-supply to the heart is increased in greater proportion than the amount of extra work thrown on the heart by a rise in the blood-pressure, the increased nutrition of the heart will cause an improvement in its capacity for meeting the added resistance, and its condition will improve; if, on the other hand, the rise of blood-pressure imposes an additional amount of *work on the heart out of proportion to the increase in* the coronary circulation, then the heart will suffer further injury. Since it is often impossible to foresee the direction which the change in circulation will take, it is better to use a small dose of alcohol and increase this cautiously if careful study of the circulation shows improvement.

Cardiac failure—not simply the actual stoppage of the heart, but the failure to maintain an adequate circulation—is often dependent *in part on faulty* respiration, and the action of alcohol in improving the respiration may react on the circulation and institute a cycle of improvement. Any improvement in the respiration which alcohol induces is usually little more than incidental, and we have other and better stimulants for the respiratory center.

It is generally admitted that alcohol is a food, but its value as a food is the subject of much uncertainty. It is not an ideal food, and even under the most favorable conditions it is utilized at the expense of injury to the organism. It must therefore be decided in any case whether the possible good will probably outweigh the harm.

Alcohol in the form of wine affords a pleasant hypnotic for occasional use, but the well-known tendency to give rise to the habit forbids the routine use of this beverage.

Alcohol is often used for bathing the skin in fever, and for hardening the skin to prevent the formation of bedsores.

(To be continued)

Therapeutics

PREVENTION IS GREATER THAN CURE

(Continued from page 743)

XXII

Measles

Measles is probably the most frequent of all infectious diseases, and as many as 25,000 cases have occurred in the city of New York in one year. No age is immune, although infants under 6 months are rarely attacked. Though measles can recur in rare instances, it generally confers immunity for life. That *it is considered such a simple, common disease* is probably the cause of the large number of deaths from neglect. It is estimated that 12,000 deaths a year occur in the United States from this disease, and the number might be much greater if some bronchial and lobar pneumonias were properly recorded as directly followed by measles. The greatest number of deaths occur in young children. While occasionally a death may occur from the intensity of the disease, generally death is caused by complications in the lungs, abdomen or ear. The complication in the ear is middle-ear inflammation with, at times, an extension to the mastoid. In the lungs the condition may be bronchial pneumonia or pneumonia; or the bronchial glands, which are probably always inflamed in measles, may become permanently enlarged. If tuberculous glands are present, general or pulmonary tuberculosis, if not considered a complication, is frequently caused by measles. The glands in the intestines may become inflamed and cause serious trouble. Inflammation of the cervical glands occurs not infrequently. Nephritis is rare. Hemorrhagic skin eruptions occasionally occur. The urine of patients suffering with measles has been shown to be toxic to guinea-pigs; therefore the toxins of this disease are circulating in the blood and pass into the urine.[1]

In civilized countries the mortality, though varying somewhat in different epidemics, is always greater where children are crowded into dark, damp tenements, and is often greater in institutions, probably from the fact that physical defects are more or less likely to be present in institutional children, or at least there is often damaged heredity. In civilized communities there has been gradually handed down more or less immunity to malignant attacks of this disease, and it has been observed that when measles first reaches uncivilized communities in which measles has not before been rampant, the death rate is exceedingly great.

Statistics show that the largest number of cases occur in the spring or late fall, and that the sexes are about equally attacked.

Anderson and Goldberger[2] have successfully caused measles in monkeys by using the blood of a patient with measles. They also showed that the nose and throat secretions may infect the monkey, but that positive results could be obtained from these secretions only when they were collected during the period of eruption. While they do not wish their deductions to be considered final, they are pretty well convinced that infection from nose and throat secretions disappears with the approach of convalescence. They did not find that the desquamating epithelium from the skin lesions carried the virus of measles.

Lucas[3] quotes Hecker[4] as finding that the virus that will infect monkeys is in the blood stream of patients with measles twenty-four hours before the appearance of Koplik's spots, and that the virus remains in the blood and can infect monkeys at least thirty-six hours after the appearance of the skin eruption. This emphasizes what has long been recognized, that the greatest infectivity of measles is during the very earliest stages, and generally before the diagnosis has been made.

Goldberger and Anderson[5] have shown that the virus of measles may pass through a Berkefeld filter, may resist desiccation for at least twenty-four hours, becomes non-infective after being subjected for fifteen minutes to a temperature of 55 C. (131 F.), and will resist freezing for at least twenty-four hours. With these scientific facts it may readily be seen why, clinically, measles is the most contagious, next to small-pox, of all diseases with which we are acquainted, and the fact that it is most contagious almost before the diagnosis can be made renders its prevention very difficult.

EARLY SYMPTOMS

It is essential, if possible, to make a diagnosis of measles before the stage of eruption. After a varying period of incubation, averaging perhaps two weeks, the first stage of measles is evidenced by an acute coryza, attended by considerable sneezing. The eyelids become swollen, and the eyes somewhat inflamed. The tonsils are generally enlarged, and the throat congested. The secretions from the nose and throat are at first serous, and later seropurulent. There is almost invariably some fever from the beginning of this first stage, varying in amount, and it is generally the highest during the first and second day of the complete eruption which, on the average, appears on the fourth day. The usual symptoms of infection are likely to be present, namely, coated tongue, loss of appetite, muscle aches, headache, some lumbar pains, chilliness, and in children sometimes vomiting or diarrhea. With the appearance of these symptoms, measles should always be suspected.

In no attack of acute illness in a child should an examination of the mouth and throat be omitted. A careful examination of the mouth will often show some punctate red spots on the hard palate, and on the mucous membrane of the cheeks will quite generally be noticed Koplik's spots, which are diagnostic. Though early described by other observers, the spots which bear his name were brought to general notice by Koplik in 1896. They most frequently occur on the cheeks near the molar teeth, and at first appear as little darker blotches on the red membrane. Soon in the center of these blotches appears a very small bluish-white speck slightly raised from the surface. These spots never seem to occur on the gums. Although there may be but few of these spots, they are typical and diagnostic of measles. Many times they are not found, but it is probably generally because they have been overlooked, or have been very few in number and minute. These spots may appear two or three days before the eruption on the skin; their diagnostic importance is therefore evident.

One should not be thrown off his guard during the first stage of measles by a sudden dropping of the temperature. This sometimes occurs without any antipyretic, and has not been explained. In other words, the illness seems, apparently, about to cease, and suddenly the temperature again rises, and soon the skin eruption is present.

The blood in measles is more or less characteristic. There is diminution in the number of leukocytes, that is, a leukopenia. Lucas[6] says that early in the infection there is distinct change in the white blood count, and that the greater diminution is in the lymphocytes. He states that a relative diminution of lymphocytes and neutrophilic cells may be noticed a week before any visible symptoms of infection occur, and that the blood will show positive evidence of this disturbance at least forty-eight hours before Koplik spots appear. He also finds a great many disintegrated cells in this blood picture. Lucas[3] also states that different investigators have shown that the eosinophil cells are diminished, and may even disappear entirely from the blood of patients during the eruptive stage of measles.

In pneumonia, in epidemic cerebrospinal meningitis, and in scarlet fever the leukocytes are increased in number. In typhoid fever and in measles there is a diminution of leukocytes, but in these diseases the greatest diminution is in the polymorphonuclear cells, while the lymphocytes may be relatively increased.

ERUPTION

This is most thoroughly described in all its details by Lucas.[3] The typical eruption of measles is papular, begins *from the third to the fifth day* (generally on the fourth), and lasts four or five days, the amount varying widely in different cases. It begins on the neck and face, then on the back, and then goes to the shoulders, arms, abdomen and legs. Besides the typical papules, there may be many macules which never reach the papular stage. The spots are generally of a dull reddish color, and somewhat resemble the bites of fleas. They may be irregular in shape and coalesce and form patches. A typical distinction from scarlet fever eruption is that in scarlet fever there is an oval clear space around the mouth. Von Pirquet[7] believes that the eruption of measles depends on the vascularity of the skin, and that the rash appears early and is more intense on the parts of the skin that have a large blood supply, and in parts that are near the large blood-vessels, and he concludes that the rash is the result of a "reaction with the measles organism or virus which takes place in the capillaries of the skin," and may be due to an agglutination of the measles organism by the action of its antibodies.

Prodromal rashes may occur in measles and cause difficulty in diagnosis. There may be an erythema not unlike scarlet fever patches. These eruptions may occur one or more days before the typical eruption of measles. They are generally urticarial in type, and often represent some acute indigestion or food poisoning, or may be due to some drug that has been administered. The diagnosis is made by the catarrhal symptoms, by the blood count, by the Koplik spots, and by the occurrence of the typical eruption of measles.

There is always more or less desquamation after the eruption begins to fade, and the more the eruption, the more the desquamation. It may last for a few days, or may last for one or more weeks. This desquamated epidermis is generally in the form of fine scales.

PREVENTION OF INFECTION OF OTHERS

As stated in the beginning of the discussion of this disease, probably few persons escape an attack of measles. Therefore, up to recent years, before isolation measures were inaugurated, most adults had had measles, and therefore were immune to the disease. With the isolation measures now in vogue, many youth and young adults have never had the disease, and therefore physicians are having more cases of measles to treat in persons who are no longer children.

A large number of cities have now declared that measles is a reportable disease, though placarding of the houses which contain the disease is not general. The isolation required by boards of health varies from fourteen to twenty-one days. A longer period than two weeks seems entirely unnecessary, as it seems probable that infection can be given only in the very early stages and apparently not longer than the stage of eruption, even by the secretions of the nose and throat. The desquamating skin does not carry contagium. Therefore, a long quarantine would seem an unnecessary hardship.

A schoolchild being reported as having measles should cause the other children in the family and tenement to be studied as to whether or not they have had the disease, and as to how close contact they have had with the infected child. It would seem unnecessary to keep children out of school who have already had this disease, since it has not been shown that there are carriers of this germ. The children who sit in school in the immediate vicinity of the infected child should also be studied, as it is positively known that the most contagious period of the disease is before the eruption, which often means, in mild cases, before it is known that the child is ill. Children who have not had the disease and who have been directly exposed to possible infection from the child who is known to have the disease should remain out of school and away from other children for a period of at least fourteen days.

It has been shown that the contagium of measles, infectious as it is, is transmitted by a more or less close contact. In the wards of hospitals measles has been treated in box compartments open at the top, without giving the contagium to adjoining beds.

The greatest danger of this disease is to young children; therefore when a schoolchild becomes infected, although the disease is almost universal in civilized countries and the majority of mankind has had it or will have it, the greatest of care must be taken that other children do not acquire this disease and later give it to infants in their households. Consequently, careful cleanliness and antiseptic measures should be used in a room in which the infected child had his desk. It is probably rarely necessary to close a school or a schoolroom on account of measles.

Physicians who are in university and seminary or boarding school towns and see a considerable number of the youth of the nation become seriously ill with such children's diseases as measles and mumps, in view of the well-known fact that these simple diseases are frequently more serious in older persons than in children, often question the wisdom of preventing the occurrence of such diseases in children. The answers to such a point of view are: 1. The more cases of measles there are, the greater will be the number of deaths, especially among infants and young children. 2. The more measles there is, the greater will be the number of permanently injured ears, in spite of good treatment.

The present hope must be that the germ of measles will be discovered and that a vaccine will be elaborated that will cause the individual to be as immune against measles as he is now immune against smallpox from cow-pox vaccination.

TREATMENT

In the first place, if the child is very young, the danger from measles is greater. Also, the death rate in the summer months is smaller than in the winter months. This is because this catarrhal disease so readily tends to cause lung and ear inflammations. As seen so frequently in many diseases, typically pneumonia, the mortality in hospital cases of children with measles is greater than in private houses, which means that such children frequently come from the unhygienic atmosphere and surroundings of tenement houses.

A patient with measles must be isolated. The room must be warm, as these patients should not be subjected to cold drafts or cold air. Chilling is especially harmful in measles. This does not mean that the air of the room should not be fresh and clean, and the ventilation the best possible.

---

[7] Von Pirquet: Ztschr. f. Kinderh., 1913, vi, 1.

Eyes.—Unless the child is very young and cannot wear colored spectacles, the room should not be dark. Sunlight is as essential for the welfare of patients with measles as it is in any other disease. It is absolutely unnecessary, in ordinary cases, to have the room black dark on account of the eyes. If the eyes are inflamed, the child will cooperate and really enjoy using colored spectacles. Of course, when it is time for the child to go to sleep, the room may be darkened, and the glasses removed.

A saturated boric acid solution may be used as a wash on the eyes, and if it seems advisable, some simple eye-drops may be used, such as:

		Gm. or c.c.		
℞	Acidi borici................		25	gr. v
	Aquae camphorae...........	15		flʒ ivss
	Aquae ....q.s. ad	25		flʒ i

M. Sig.: Use as eye-drops three or four times a day.

If the lids tend to stick together after sleeping, they should be gently washed with warm boric acid solution or plain warm water, and before the child goes to sleep the edges of the lids may be anointed with thick white petrolatum.

Cough, Etc.—If old enough, the child should gargle several times a day with some simple, warm, alkaline sedative solution. If the child is not old enough to gargle, the throat should be sprayed. The nose should also be sprayed occasionally, if it seems stopped up. However, it is often well to leave the nose alone in measles. Most nasal douching is inadvisable, as tending to force fluid or secretions into the eustachian tubes.

Most of these patients require some simple expectorant mixture, although many physicians are losing faith in the activity of so-called expectorant drugs. There is no safe drug that promotes the secretion of the mucous membrane of the upper air passages and bronchial tubes more than does ammonium chlorid. It is of advantage in causing the cough to be less dry, and therefore aiding the expulsion of any mucopurulent matter that may be in the trachea and bronchial tubes. Also, if the cough is excessive from irritation, a sedative should be added to prevent the unnecessary coughing. A child 5 years old may receive the following:

		Gm. or c.c.		
℞	Codeinae sulphatis.........		05	gr. i
	Ammonii chloridi..........	3		ʒ i
	Syrupi tolutani...........	50		flʒ ii
	Aquae ....q.s. ad	100		flʒ iv

M. Sig.: A teaspoonful, in water, every two or three hours, when the child is awake.

If the child's cough is not excessive or irritable, the codein may be omitted from the mixture. As soon as the expectoration is more free and there is no excessive amount of coughing, the medicine may be stopped. A child 10 years old should receive twice the amount of codein sulphate, and the ammonium chlorid should be increased to 5 gm., and if deemed advisable, the sour sirup of citric acid may be substituted for the sweet sirup of tolu in amount of 25 c.c. to the 100 c.c. mixture.

Bowels.—In the beginning of the disease, the child should receive a small dose of calomel, 0.05 or 0.10 gm. (1 to 1½ grains) given with milk; or a dose of castor oil, or some rhubarb or cascara; at least, the bowels should be thoroughly and well moved. Minute doses of calomel frequently repeated should not be given, as such dosage causes irritation and no benefit. Subsequently the bowels should be moved daily with some gentle laxative, if such is needed.

Diet.—The food depends on the temperature, and should be liquid and simple as long as the temperature is elevated. As soon as the temperature falls to normal, the child should receive good nutritious food, and plenty of it. It is inadvisable to give meat in any form, including broths, as long as the eruption is present. If, as has been suggested, the eruption in measles is caused by some irritant circulating in the blood, such as occurs in urticaria, representing a sort of anaphylaxis, the proper diet comprises cereals, milk, and plenty of water. Such little patients are better without fruits, as sometimes even orangeade or lemonade seems to cause more itching and discomfort of the skin.

Fever.—The temperature rarely calls for much treatment. If it is high, however, one or two doses of acetanilid will generally be sufficient to reduce it. Hot sponging will cool the child as much as cold sponging will, and with less disturbance. Cold sponging in measles is inadvisable. As often as the child is bathed or sponged for temperature, the surface of the body should be powdered with some bland talcum.

Skin.—Unless the room is cold and damp, or the patient is otherwise ill, a cotton nightdress will cause less itching and discomfort than would a warmer flannel or silk shirt. All through the illness the nurse should recognize that it is the secretions of the nose and throat that cause infection of others, and not the eruption or exfoliation from the skin. This does not mean that it is not necessary to sterilize the child's garments and bedclothing, as such may carry the infection from the nose and throat.

Convalescence.—Prolonged, careful convalescence is essential in measles. Measles, like whooping cough, is often a forerunner of pulmonary tuberculosis. Probably no attack of measles ever occurs that does not cause enlargement and more or less inflammation of the bronchial glands. If such glands harbor tubercle bacilli, they are stimulated to cause an acute infection. On the other hand, immediately after an attack of measles a patient is doubtless more susceptible to infection from tubercle bacilli. Therefore, before the child is returned to school the cough should have ceased, his weight should be normal, and his nutrition should be good.

Persistent enlarged glands in the neck or elsewhere, and adenoid conditions or enlarged tonsils, should all be regarded with suspicion. Such conditions are liable to be accentuated by an attack of measles, and proper treatment should be instituted. A suppurating ear must be treated by a specialist until pronounced cured and the hearing is as near perfect as possible. The physician should remember that most defective ears follow measles, scarlet fever and influenza; that an acutely infected ear, if immediately correctly treated, is generally saved intact; distention and perforation may occur without pain. Consequently, he should be ever alert to see that the complication of middle-ear inflammation is immediately treated.

CURRENT ASPECTS OF MILITARY SURGERY

Although there is no dearth of news from the front in the present European conflict, it can scarcely be said that there has been a surfeit of authentic information relating to the medical features of the great campaigns that are taking place abroad. The leaders in medicine and surgery most competent to report the situations that confront the medical organizations of the enormous armies in the field have been too busy with the immediate demands of the thousands of sick and wounded and with the problems created by new conditions of warfare. The helpful tasks of literary-scientific retrospect and review must be postponed until the future, when a secure peace will afford an opportunity to learn in fuller measure the lessons which the experience of the medical staffs affords.

An occasional glimpse of the real state of affairs seen with the eyes of the expert at this early date is, accordingly, of more than incidental interest. For this reason we record some of the impressions which Professor Tuffier, the Parisian surgeon, has lately communicated.[1] At the outset it must be recognized that the questions of paramount importance in the surgery of the wounded involve, first of all, the prevention or diminution of sepsis; secondly, promptness of treatment, and thirdly, transport of the wounded from the firing line to the base hospitals in ways that are as humane and as little harmful as the conditions will permit. Obviously an ideal management of the situations which are created is never possible; for, as has been remarked by a keen observer of the work of many battlefields, from the point of view of the commanding generals, the patients are merely a part of the unfortunate and inevitable waste of war, and cannot be allowed to take precedence over supply trains for the troops in critical moments.

"I desire to do honor," Tuffier writes, "to the teachings of two great French surgeons, Chassaignac and Lucas-Championnière, the triumph of whose theories is henceforth incontestable—namely, the superiority of the method of antisepsis over that of asepsis, and the drainage of infected wounds at the most dependent angle." This quotation will serve to indicate the direction and intent of much of the surgical work of more immediate importance. With non-closure of wounds as a rigid rule, and with an unremitting watchfulness for evidences of insidious acute septicemia or gangrenous emphysema which may demand major operative intervention, the tendency of the French surgeons has been toward a primary conservative surgery of the limbs instead of treatment by amputation. The more frequent injuries are caused by rifle bullets, shrapnel and shell splinters. The part played by the latter in the development of the most dangerous wound infections is so great that immediate extraction of the splinters is of the first importance. Bullet wounds are usually less formidable, as has been recognized for some time in military surgery. Under the modern system, after extraction of superficial splinters, cleansing of the wound, and local dressing, the patients with complicated fractures, as well as those with bullet wounds of the chest, can usually be transported successfully from the station of departure to the larger hospitals, where further extensive surgical intervention is often quite unnecessary.

A far more difficult surgical problem is presented by the wounds of the abdomen. Laparotomy and suture of the intestine seem impossible with any chance of success in surroundings where septic cases abound and where men are arriving every minute with wounds of all degrees of severity demanding immediate examination and treatment. At most, if percussion shows the presence of a large intra-abdominal effusion, as it often does, a suprapubic incision may be made under local anesthesia and the wound drained. The whole treatment of abdominal wounds at the field hospital—the first clearing house for the wounded—resolves itself into this: to keep the patient in a sitting position and without food, until he arrives at a hospital provided with suitable facilities for further treatment.

As has been expected, tetanus is the great complication of wounds received in battle. It is at present seen in every grade of military hospital. In the great majority of cases, Tuffier assures us, inoculation occurs on the field of battle and only exceptionally in the hospital wards. The most frequent sources of tetanus are shell wounds, wounds soiled with earth, and wounds of the fingers and toes. It has been suggested that inasmuch as many of the wounded are returned from the front in cars that have been occupied by horses, and since these animals are known to harbor the tetanus bacilli, a prominent source of infection is hereby afforded. Inoculation in this way is, of course, theoretically possible; but in view of the protective dressings which the wounded carry and of the non-selective distribution of the infection, it is hardly probable that the railroad trucks are the real pathogenic factor. Tuffier is convinced that patients presenting no specific symptoms are not infrequently carriers of the tetanus bacillus on the surfaces of their wounds.

---

[1] Tuffier: A Contribution to the Study of Military Surgery, Brit. Jour. Surg., 1915, ii, 449.

The counsel of perfection—the destruction of microorganisms in a wound by means of the first dressing—can rarely be carried out adequately at the front. Antitetanic serum must therefore be used at the earliest possible moment. Tuffier argues that tetanus must be attacked on the field of battle where it originates, and it is there that antitetanic serum should show its value. He even believes that the available supply should be employed for the newly wounded, and systematically injected before the first dressing is applied. Only the surplus should be furnished to hospitals in the rear; for, Tuffier[1] writes, "at the present time we have not an instant to lose; tetanus is our most cruel enemy, and this measure ought to give us the maximum chance of success."

The unexpected frequency of gangrenous emphysema in the present war has already been pointed out in THE JOURNAL.[2] The management of this treacherous infection, even with free incisions and cautery along with deep injections of hydrogen peroxid, is at best insufficient. Preventive treatment — the removal of the foreign substance carrying the septic material into a hidden part of the body without an adequate drainage outlet—must be depended on to reduce the prevalence of the infection.

The unparalleled exigencies of the present war are responsible for more than wanton waste and cruel suffering. They give rise to an undeniable mental depression under conditions in which, despite the most commendable courage and endurance, the guarded traditions of success in surgery are overthrown and the highest scientific skill is hampered by the impossibility of exhibition. It is due to our colleagues at the front that the shortcomings of military surgery should be charged to their real source.

THE SUSTAINED INTEREST IN THE PROBLEM OF TUBERCULOSIS

The National Association for the Study and Prevention of Tuberculosis reports that $20,700,000 was spent last year in combating this disease in the United States.[3] Notwithstanding the immense sums expended, it is doubtful whether we are getting our money's worth in lowered death-rate, which is, after all, the final criterion by which the success or failure of the antituberculosis campaign must be determined. The seriousness of the problem is recognized by leaders of thought and activity in other vocations than medicine. Notable among these is Governor Craig of North Carolina, who devoted a considerable portion of his annual message to the subject.[4] His state has 18,000 cases of tuberculosis known to the health authorities. He estimates that the entire revenue of the state would be insufficient to care for all its tuberculous victims in sanatoriums, and he urges that some means be found to help those who cannot be accommodated in institutions.

Most of the legislation so far enacted for the control of the disease has tended to exaggerate the dangers from casual exposure, and to emphasize the value of segregation in sanatoriums at the expense of every other consideration. Evidence accumulates daily that tuberculosis is a house infection or family disease, and that the proper way to stamp it out is to remedy the home conditions which predispose to it. That it is preeminently a disease produced by intimate rather than casual contact is shown by recent investigations of the Public Health Service[5] and also by Lampson's survey of tuberculous families made for the Minnesota State Board of Health.[6] Carrington, Foster and Sweet of the Public Health Service studied the influence of the migrant consumptive on the health of the community to which he moves. These studies were conducted in North and South Carolina, Texas and New Mexico, and in none of the communities frequented by tuberculous persons in search of health was there the slightest indication of the spread of the disease from them to the native population. Lampson's investigation of the spread of the disease was an intensive study of tuberculous families in five Minnesota counties. A list was made of all deaths from tuberculosis for the year 1911 and previous to Aug. 1, 1912, and the surviving members of the families were then examined for evidences of the disease. Whenever there were no tubercle bacilli in the sputum, or positive physical signs, the von Pirquet test was used. Ninety-seven families were studied, and for individual members of these families 449 charts were made, which indicated the findings under the following heads: name, sex, age, nationality, social condition, school attended, height, weight, general appearance, nutrition, exposure, lungs, bones, joints, skin, glands, sputum, pulse, temperature and respiration. These results were tabulated to show the amount of infection from (*a*) complete exposure, that is, intimate exposure for a long time; (*b*) partial exposure, when the patient was away for part of his illness, or members of the family were away during that illness, and (*c*) doubtful exposure, when reported death was apparently from some other cause than tuberculosis.

While the amount of material is not large, the striking uniformity of results in the different locations adds weight to the findings, which were substantially as follows: Complete exposure of families resulted in a positive von Pirquet reaction in 79 per cent. of the surviving members of those families, whereas in partial exposure *the positive reactions were only 28 per* cent. In those classified as doubtful exposures, the positive reaction was still less frequent, only 8 per cent. of these showing evidences of infection. In the families exposed to pulmonary tuberculosis, 70 per cent. of the members showed signs of infection, and in those exposed to non-pulmonary tuberculosis 32 per cent., while in the non-tuberculous families only 8 per cent. presented any evidence of the disease.

In view of the increasing evidence that both the predisposing causes and the successful treatment of tuberculosis are inseparably bound up with the problems of the home, it is to be hoped that at least a part of the sustained interest in the subject be directed toward a rehabilitation of tuberculous families rather than ill-advised segregation of individual members.

THE HARRISON LAW A NATIONAL OBLIGATION

Both newspaper comments and professional criticisms indicate that there is much misunderstanding of the Harrison law, which has just gone into effect. Many physicians have *not fully grasped its purpose.* A brief statement of the history of the law may, perhaps, be of value.

The Harrison law is not the result of any sudden spasmodic impulse on the part of Congress. It is, on the contrary, a part of a carefully considered program for the control of the traffic in habit-forming drugs and especially in opium. This movement is not confined to this country; it is international, although the United States, it is a pleasure to record, has been the leader in the movement. It has been a part of the established policy of our government since the earliest relations with China and other oriental nations to discourage the opium traffic in the Far East. As early as 1833, a treaty with China forbade any American citizen engaging in the opium trade. In 1906, China began earnest efforts to crush out this evil. To aid her in this, the United States initiated an international movement to secure the cooperation of the leading Western nations. As a result, there met at Shanghai in February, 1909, the representatives of thirteen nations, comprising Austria-Hungary, China, France, Germany, Great Britain, Italy, Japan, the Netherlands, Persia, Portugal, Russia, Siam and the United States. This conference resulted in the establishment of the International Opium Commission, appointed to study the entire question and to submit recommendations. The next step was taken Dec. 1, 1911, when a conference of the powers represented in the Shanghai Commission was held at the Hague. Jan. 23, 1912, the members of the conference signed an agreement for a strict regulation of both national and international traffic in opium, morphin and cocain. To the carrying out of the program for the restriction of habit-forming drugs, *not only is our national* honor pledged, but also as leaders in this movement, it is the plain duty of our nation to initiate such legislation as may be necessary.

For the carrying out of our international obligations, three bills were drafted. The first, H. R. 1966, prohibited the importation of opium for any other than medicinal purposes. The second, H. R. 1967, prohibited the manufacture of smoking opium in the United States. Both of these bills became laws over a year ago. As there are only a few firms in the country which import opium and none which manufacture it, these laws affected a limited number of persons and so attracted little public comment. The third bill, H. R. 6282, which became a law Dec. 17, 1914, is the Harrison law, now going into effect. In various forms and under different names it has been before Congress for nearly six years. It does not forbid the sale of habit-forming drugs. Only state laws can do that in this country. It restricts traffic in them to persons engaged in legitimate businesses in order to make it possible to trace these drugs from the importer to the ultimate consumer. The suppression of illegitimate traffic in these drugs can be accomplished only by state laws properly drawn and enforced.

The object to be attained is the world-wide restriction of the use of opium and cocain to their proper medicinal purposes. In securing this, the sympathy and support of every right-minded man and woman should be forthcoming. But physicians, especially, as those who know better than any other class the dangers and ravages of drug addictions, should endorse and support in every way this effort for the uplifting of humanity, to which our national honor is pledged.

THE PHYSICIAN AND THE HARRISON NARCOTIC LAW

From the large number of inquiries received, it is evident that many physicians are in doubt as to what they are required to do under the Harrison law and what the law will do to them. So many misstatements on this subject have appeared that a brief summary of the purposes and requirements of the law may be reassuring.

The law affects the physician both as a prescriber and as a dispenser of drugs. The only effect it has on the former—the prescribing physician—is that it requires him to register with the collector of internal revenue of the district, and that in writing a prescription for narcotic or habit-forming drugs he must write thereon the name and address of the patient, have on the prescription his office address and his registry number, and sign his name in full. He can—and should, probably, if he has printed blanks—have his registry number printed on the blank. He need not keep either copies or records of prescriptions; this is done by the druggist. These prescriptions cannot be refilled. This is all there is to the Harrison narcotic law so far as it affects the prescribing physician. The only expense is in securing his license once a year, at a cost of one dollar. And the only facts to be kept in mind in writing prescriptions are that the patient's name and address must be written thereon and that the physician must sign his name in full—precautions, however, that should be taken on all prescriptions.

If the physician desires any of the specified drugs for his own use, he must then make out an order for them on a blank form bearing his registry number. These blanks are furnished by the Internal Revenue Department in packages of ten for ten cents. The physician cannot order drugs for his own use on a prescription blank.

If a physician is in personal attendance on a patient, he can administer any treatment he sees fit in the form of hypodermic injection, sprays, applications, etc. If he orders a nurse to give such treatment, then the written order must appear in the history sheet with the physician's initials. The statement recently appeared in a druggists' journal that an official ruling had discriminated between a visit to the patient at his home and personal treatment of a patient by a physician at his office, and that one was personal attendance and the other was not. This statement is without foundation. No such ruling has been made.

If a physician dispenses his own drugs, then he must conform to the same restrictions as a druggist. He must order the drugs specified by this law on the blanks furnished by the internal revenue collector, and he must keep a record of the dispensing of such drugs, the date, the quantity and the name and address of the person to whom they were given. This record must be kept in a "suitable blank book," and must be preserved for two years. Drugs dispensed while the physician is in personal attendance on the patient do not need to be recorded. Neither do preparations which do not contain more than 2 grains of opium, ¼ grain of morphin, ⅛ grain of heroin or 1 grain of codein.

These provisions are simple and need cause the physician little annoyance. The great majority of physicians write prescriptions. Physicians who dispense, only occasionally dispense preparations of narcotic drugs. The restrictions for both classes are simple and easily observed. The cost for all physicians is the same, a nominal fee for registration, a small cost for order blanks. Additional rules may be found necessary as the law is enforced, but there is at present nothing that need cause physicians any inconvenience or annoyance.

But what about old habitués, persons suffering from painful and incurable diseases, and others to whom opium in some form is absolutely necessary? Every physician knows of such cases. For them the physician so long as he complies with the law of his own state can prescribe whatever he sees fit. But it must be done openly and without attempt at evasion and the physician must be ready and able at any time to justify his acts. The whole purpose of the law is to restrict the use of opium and cocain to legitimate channels.

THE PREVENTION OF INFANTILE SCURVY

The widespread employment of pasteurized milk and the growing use of this food in the dietary of young infants have brought with them certain inherent dangers which need to be recognized quite as clearly as the advantages of the pasteurization process are appreciated. It is not the intention to discuss at this time the reasons which are responsible for the current practice in the treatment of most milk prior to its distribution before use. The arguments are well known to the majority of the members of the medical profession and they have won the approbation of most hygienists. The feeling of safety against serious infection has an undoubted justification in the present organization of the milk industry.

There are, however, attendant dangers which should be widely known because they are easily averted. Infantile scurvy may readily develop in infants that are fed largely, if not exclusively, on pasteurized milk. This is true not only when the milk is heated carefully to a temperature of 165 F. for twenty minutes, but also with the product obtained after the more conservative pasteurization at only 145 F. for thirty minutes.[1] Pasteurized milk may not be the sole factor in the production of infantile scurvy; but the important rôle which it plays has been shown by the prompt disappearance of all symptoms when unheated milk is substituted for the pasteurized milk, the formula and amount of food remaining unchanged. For these facts there exists the evidence of careful observers.[1]

We are aware that the French clinicians in particular oppose the charge that the heating of milk can produce a product which may develop scurvy. Boiled milk appears to have been fed by them without detriment in thousands of cases. Nevertheless, Hess and Fish point out that whatever the explanation of such results may be, it must be remembered that these statistics refer to patients treated in dispensaries, and that they were not observed under ideal conditions. There can be no doubt that milk loses some of its antiscorbutic qualities as the result of heating, though the cases that develop from the use of a food pasteurized at 145 F. may be rather mild. They may show petechial hemorrhages, some tenderness of the bones, a very slight degree of peridental hemorrhage, yet fail to evince any tendency to progress. In such instances Hess and Fish suggest that there seems to be almost, if not quite, a balance between the demands of the body and the supply in the diet of the essential substances concerned in the scorbutic phenomena.

---

[1] Hess, A. F., and Fish, Mildred: Infantile Scurvy; The Blood, The Blood-Vessels and the Diet, Am. Jour. Dis. Child., December, 1914, p. 385.

The use of antiscorbutics in these cases is, of course, a procedure familiar to all pediatrists. The general practitioner is more often oblivious of both the dangers lurking in the exclusive use of heated milk and the corrective agents which are available. Although raw milk contains sufficient of the essential substances to prevent the development of scurvy, its antiscorbutic potency is mild compared with what has been termed the "miraculous change" which is brought about by giving orange juice. One ounce of this given daily suffices to avert nutritive disaster.

Hess and Fish[1] have acquired some interesting new experiences in relation to this potent antiscorbutic, which is so widely available and easily administered to children at all ages. The efficacy of vegetables is distinctly inferior to that of orange juice. Satisfactory results appear to follow the routine use of orange juice that has been boiled five to ten minutes. It is surprising that heat apparently does not lessen the therapeutic value in the case of this fruit product, because studies on animals subjected to experimental scorbutus[2] have indicated that the antiscorbutic property of such plant materials as cabbage is readily destroyed by cooking.

It appears further from the experience of Hess and Fish that the juice of orange peel, prepared by extraction with water and sugar, serves the same purpose as the liquid expressed from the interior of the fruit. This means an economy in large institutions. Potato—not potato flour—likewise has been found efficacious, though not in the same rapid degree as orange juice. It is suggested that this vegetable may be added to pasteurized milk as potato-water (made by boiling potato in water) instead of the barley-water which is now commonly used as a diluent. This is in harmony with the fact that epidemics of scurvy in adults have been reported in countries where the potato crop has failed.

Not long ago the potency of butter-fat, egg-fat, and cod liver oil in facilitating the growth of young rats under conditions of diet adequate in respect to energy but lacking some growth-promoting factor was pointed out in connection with the nutrition studies of McCollum and Davis and Osborne and Mendel.[3] Hess and Fish have found that cod liver oil did not prevent the development of scurvy in infants. This distinction should be borne in mind in connection with the current discussion of "vitamins" and diet deficiency diseases.[4] The substances concerned in the prevention of scurvy and beriberi, or in the promotion of growth presumably have no direct relation to each other; and however essential to life they may be, we are not yet in a position to group them collectively into association with so promiscuous a category as the proposed "avitaminoses" of Funk. Each deficiency must be studied independently.

Incidentally, the desirability of having some helpful guide to the onset of scurvy leads us to quote the proposed "capillary resistance test" of Hess. It consists in subjecting the capillaries and vessels of the arm to increased intravascular pressure, by means of an ordinary blood-pressure-band, and of observing whether this strain results in the escape of blood through the vessels—the appearance of petechial hemorrhages into the skin. The vessels of normal infants were found to withstand, without apparent disturbance, 90 degrees of pressure for three minutes, whereas the vessels of infants suffering from scurvy gave way under this pressure. The test is not specific for scurvy, but is a method of demonstrating a weakness of the vessel walls, whatever may be its cause.

REASON FOR THE FAITH WITHIN US

Sometimes, though not often, we are asked why The Journal does not "let up" on the subject of fraud in medicine, especially as it applies to the "patent medicine" evil. Our best answer to such an inquiry would be to ask the person making it to spend a few days in this office and read some of the letters that come from the public and the profession relative to the subject. This, of course, is impracticable, and the best we can do is, occasionally, to give such letters publicity. Many of the communications of this type—and therein lies the tragedy of it—are privileged and could not with propriety be printed. Some, however, are available. The two letters that follow are from widely different sources, the first from a physician in Tennessee and the second from a woman in New Hampshire. While, in a way, they deal with subjects that are as widely separated as their geographical sources, yet they both point in the same direction and they both call for a common remedy. Here is the letter from Tennessee:

> "The exposure of Wine of Cardui alone is enough to cause any doctor who has the interest of humanity at heart to subscribe to The Journal. If he can't justify it any other way, call it charity. Many a poor, hard-working man has come home at night, compelled to spend his last dollar for the nostrum in order to satisfy his suffering wife's mind—and keep down the gossip of neighbors who might say he refuses to buy medicine for his wife—even though he knows it is a fake of the eighteen carat type. That man has been saved untold mental anguish, and the absolute necessities of life, in having you come to his rescue. May The Journal keep up the fight. We are with you."

The point raised by the doctor exposes the rottenness of the nostrum business from a new angle. There is no doubt that the problem he presents is by no means an uncommon one, especially in the rural districts, and among the poorer classes. Nostrum manufacturers frequently refer to their preparations as the "poor man's medicine." In the same way the beneficiaries of the low-grade commercial medical schools have called these institutions the "poor boy's school"; and in the same way, too, the manufacturers of adulterated and sophisticated foodstuffs try to justify their products by referring to them as the "poor man's food." The argument is as fallacious in one as in the others. The woman from the New England village wrote:

> "My husband has had tuberculosis of the spine for two years and used the 'cast treatment' but was persuaded to use 'Yonkerman's Tuberculozyne' taking four, yes, I think five treatments as a strength and health builder but quit it three or four months ago, as it did not cure. . . ."

Yonkerman is a horse-doctor and his "Tuberculozyne"[1] is one of those wretched consumption cure frauds that lure the ever-hopeful consumptive to destruction. It is letters of this kind, coming in almost daily, that give an all-sufficient answer to the query propounded at the outset.

NEW YORK'S NEW SANITARY CODE

Under the new health law in New York, enacted in 1913, a public health council is created whose duties, among other things, is to establish sanitary regulations dealing with "matters affecting the security of life or health or the preservation or improvement of public health" in the state outside of New York City. The council consists of the commissioner of health and six appointive members who share with the commissioner responsibility for health regulations. They are charged with the duty of prescribing the qualifications of directors of divisions, sanitary supervisors, public health nurses, registrars of vital statistics and local health officers. In the first report of the council issued as a part of the Thirty-Fifth Annual Report of the State Department of Health for 1914, it is said that in framing the sanitary code the council aimed to secure "the advantages which science and experience, especially during the last quarter of a century, have offered in the prevention of disease and in the promotion of the common welfare, with the least possible interference with the business, comfort and convenience of the people concerned." Heretofore the enactment of sanitary regulations has been exercised by over fourteen hundred local boards of health with consequent lack of uniformity and effectiveness. Under the present law the state is divided into sanitary districts in each of which a sanitary supervisor counsels and assists the local health officers in carrying out the provisions of the code established by the council. So far seven chapters of the code have been enacted, the first covering definitions and general provisions; the others relate to communicable diseases, production and handling of milk and cream, the practice of midwives, labor camps, nuisances, and miscellaneous subjects such as spitting, the common drinking cup, the common towel, barber shops, etc. It will thus be seen that the code as so far provided covers many of the important features of public health regulation and disease prevention. The outstanding and most valuable feature of the law providing for the council is the uniformity secured by the establishment of a code governing all health bodies, particularly as applied to the handling of epidemics of the communicable diseases, the protection of milk and food supplies, etc. Elasticity is given to the code by the provision that regulations in addition to those prescribed by the code may be made by local health bodies, provided they do not contravene the provisions of the general code. In framing the code, the council states that it has attempted to make it comprehensible to the citizens, not burdensome, and has eliminated useless sanitary procedures and obsolete quarantine regulations. The seven chapters of the code are set forth in the report.

THE SOURCES OF ENERGY FOR THE HEART

There is a prevailing sentiment, based on convincing experiments gathered during several decades, that, under ordinary circumstances of diet and environment, muscular activity has hardly any influence on the metabolism of the proteins. The source of energy for the contraction of our muscles is in general to be sought in non-protein stores of supply, particularly in carbohydrates. Every text-book teaches these now familiar facts, although the dietary practices of the athlete and his "trainer" often are at direct variance with the suggestions of the science of nutrition. A striking way in which to demonstrate the nature of the energy metabolism of muscle is furnished by the surviving isolated heart, which can now literally be made to beat for hours and even days after its separation from the organism. From experiments with such a test object engaged in characteristic work, it has become plain that carbohydrate is used up by the contracting cardiac musculature. Although the evidence already obtained with contracting isolated muscles has been negative with respect to the participation of proteins in its energy requirement, the newer facts of the chemistry of nutrition have seemed to warrant added trials. Now that the modern researches have made it clear that the nitrogenous intake reaches the tissues, including the musculature, in the form of amino-acids, the rôle of these compounds as the immediate representatives of the nitrogenous pabulum remained to be investigated. Buglia[1] has accordingly perfused surviving hearts with Ringer's solution to which representative amino-acids — glycocoll, alanin, tyrosin, aspartic and glutamic acids, asparagin or glutamin — were added in various concentrations. Despite the continued functioning of the musculature, neither the added nitrogenous substance nor any of those present in the cardiac tissue itself were indicated by Buglia's analyses as having been used. The expected happened.

---

[1] This fraud is described in the pamphlet "Consumption Cure Fakes," price 10 cents.

[1] Buglia, G.: Déterminations d'azote titrable au formol dans le liquide qui a circulé à travers le coeur isolé de mammifère, Contribution aux recherches sur l'exchange azoté du tissu musculaire, Arch. ital. de biol., 1914, lxi, 277.

yet fail to evince any tendency to progress. In such instances Hess and Fish suggest that there seems to be almost, if not quite, a balance between the demands of the body and the supply in the diet of the essential substances concerned in the scorbutic phenomena.

The use of antiscorbutics in these cases is, of course, a procedure familiar to all pediatrists. [1] Buglia, G.: Déterminations d'azote titrable au formol dans le liquide qui a circulé à travers le coeur isolé de mammifère, Contribution aux recherches sur l'exchange azoté du tissu musculaire, Arch. ital. de biol., 1914, lxi, 277.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

ARKANSAS

College Gets Appropriation.—The Arkansas legislature has made an appropriation of $65,000 for the Medical Department of the University of Arkansas for the next biennium. It has also passed a bill providing for the erection of a state hospital at Little Rock to be conducted in connection with the medical department of the university.

GEORGIA

Medical Society Reorganized.—At a meeting of physicians of Mitchell County, held at Pelham, February 19, the Mitchell County Medical Association was reorganized and the first meeting will be held at Camilla on March 10.

Atlanta Neurologists Organize.—The Atlanta Neurological Society was organized February 11, with the following officers: president, Dr. E. Bates Block; vice-president, Dr. Hansell Crenshaw; secretary, Dr. Lewis M. Gaines. The society will hold its meetings on the second Thursday of each month.

Hospital Happenings.—A charter was granted on February 13 to the Cooperative Hospital Association, Atlanta. The organization has already leased a building in Atlanta for its work. The plan of the hospital is to furnish hospital treatment to persons who are unable to go into the pay wards of other hospitals.——The new university hospitals erected at Augusta at a cost of $500,000 have been turned over to the city by the contractors and the formal opening will occur about March 15.——A new site has been selected for the Georgia Baptist Hospital, Atlanta, and plans have been made for new buildings to accommodate about 500 patients. A new medical staff has also been selected.——The Hospital for Negroes, established by William H. Thomas at Rome is nearing completion. The ultimate plan of the hospital is to have cottages in addition for male and female patients, for a maternity hospital and for a hospital for children.

ILLINOIS

Hospital Dissolved.—The stockholders of the Amboy Hospital Company, at a recent meeting, voted to dissolve the corporation and on February 27 the building was sold at public auction.

State Board Will Provide Nitrate of Silver.—It is announced that the State Board of Health will shortly be ready to supply local physicians with silver nitrate in individual tubes for the avoidance of ophthalmia neonatorum.

Chicago

Personal.—Dr. Leigh K. Patton, an intern at Cook County Hospital, fell in an elevator shaft in the institution, February 24, fracturing his skull and right arm.—Drs. Greene V. Black, Truman W. Brophy and Eugene S. Talbot were awarded the degree of Doctor of Science at the dedicatory exercises of the Evans Museum and Dental Institute of the University of Pennsylvania, February 22.

INDIANA

Eugenics and Free Lunch Defeated.—The state legislature has defeated the eugenic bill, but has passed a bill to abolish the free-lunch counter in the saloons. The inspection made by the State Board of Health showed the free-lunch counter to be most insanitary.

Filtration Plant Ordered.—The public service commission has ordered the New Albany Water Company to install a filtration plant. The State Board of Health ordered this some time ago and was ignored by the city council, but after having evidence from Dr. John N. Hurty, Indianapolis, secretary of the State Board of Health, that samples of the Ohio River water showed typhoid bacillus, the order was issued.

Dental Clinic Appropriation.—The Indianapolis Board of Health has appropriated $500 to pay for material used in the work for schoolchildren at the dental clinics, and $300 has been appropriated for the use of spectacles for children who need them and whose parents cannot afford to buy them. The board has also signed a contract with the Indiana University School of Medicine under which, for the sum of $975 a month, the school agrees to maintain the city dispensary.

Child Welfare Exhibition.—During the week of February 16 to 25, a child welfare exhibit was held in Tomlinson Hall, Indianapolis, and was well attended. The exhibit was divided into numerous topics, among them being housing and homes, schools, moral and religious life, kindergarten, health, child labor and conservation of vision. A series of illustrated talks were given on the subject represented. In a central court there was a continuous program of drills, gymnastics and folk dances and four smaller courts were devoted to school work, domestic science, manual training, kindergarten, rural schools, and a model school room. The organization had for its head Dr. Frank B. Wynn, and the director of all the exhibit was Dr. W. F. King. Practically all the physicians of the city cooperated in making the exhibit a success. It is the intention to have the exhibit become a permanent one for use throughout the state.

Hurty Anniversary to Be Celebrated.—The Indianapolis Medical Society, at its meeting February 23, adopted a resolution suggesting a celebration March 12, to commemorate the nineteenth anniversary of Dr. John N. Hurty as state health officer. Dr. Frank B. Wynn, Indianapolis, president of the state society, and Drs. David Ross and Alfred Henry, president and secretary of the Indianapolis society, were named a committee to arrange a suitable observance of the anniversary.

During the past week Dr. Hurty was elected president of the Indiana Sanitary and Water Supply Association at its annual meeting. These justly deserved honors to Dr. Hurty are apropos, as the state legislature is now considering a bill which would make the state health officer a political appointee. The leading newspapers of the state have had scathing editorials denouncing this form of legislation.

IOWA

New Hospital Opened.—The Primghar Hospital was opened for inspection February 12 and 13; on February 14 dedicatory services were held, and the hospital was opened for the reception of patients on February 15.

Personal.—Dr. Campbell Palmer Howard, professor of medicine in the University of Iowa, Iowa City, has been granted an indefinite leave of absence and will leave for Montreal, February 27, to join the McGill General Overseas Hospital, Montreal, which will go to Europe next month. Dr. Clarence E. Van Epps will look after Dr. Howard's work in his absence.——Dr. M. Charles Mackin, assistant physician at the Clarinda State Hospital, has been appointed superintendent of the Iowa State Institution for Inebriates, Knoxville.——Dr. Joseph C. Ohlmacher, Clarinda, will succeed Dr. Mackin as first assistant physician at the Clarinda Hospital, and Dr. Roscoe D. Smith, third assistant physician, has been promoted to second assistant physician.——Dr. William S. Parks, Brighton, who has been operated on recently, has recovered and resumed practice.——Dr. George W. Yavorsky, Belle Plaine, has been appointed local surgeon for the North-Western System, vice Dr. James B. Cox, Belle Plaine, deceased.——Dr. Beth Vincent, Boston, has started for Europe to work in the American Ambulance Hospital, Paris.

KANSAS

Division of Fees.—A bill forbidding the secret division of physicians' fees has been introduced into the House of Representatives. It provides that no physician or surgeon shall pay or offer to pay to any other physician or surgeon any fee for patients brought to him for treatment nor receive any fee for sending patients to other physicians. Division of fees for professional services where made with the full knowledge of the patient or the person paying the bill is exempt. In a word, the bill is aimed at the secret division of fees between general practitioners and specialists, surgical or otherwise. A penalty of a fine of not more than $500 or imprisonment in the county jail for six months or both and the revocation of the licenses of the convicted persons is provided. Hospitals or clubs owning or operating hospitals are included within the provisions of the act which has been reported favorably by the house committee.

MARYLAND

Conference of Charities and Corrections.—The National Conference of Charities and Corrections will be held in Baltimore from May 12 to 19, inclusive.

Health Lectures for Negroes.—The Public Health Conference recently held proved so successful that it has been determined to hold a series of lectures on health topics for negroes exclusively.

MASSACHUSETTS

Summer School.—The Boston University School of Medicine announces that it will conduct a summer school for graduates in medicine from May 3 to June 12. Courses will be offered in dermatology, digestive diseases, gynecology, neurology, otology, obstetrics, orthopedics and pathology. Thirty-six members of the medical faculty will constitute the faculty of the summer school.

Personal.—Surg. Richard H. Creel, U. S. P. H. S., has declined the offer of Mayor Curley of Boston to make him head of the reorganized Boston Health Department, as the surgeon-general finds it impracticable to grant Surgeon Creel the necessary leave of absence.——Dr. John H. McCollom, Boston, for many years connected with the Boston City Hospital, retired February 15.——A banquet was tendered Dr. Herman C. Bumpus, the new president of Tufts College, by the medical and dental schools of the college, February 8. Dean Charles F. Painter, Boston, of the medical and dental schools was toastmaster.——Dr. George B. Magrath, Boston, has been reappointed medical examiner of Suffolk County.

Hospital Dedicated.—The Chapin Memorial Building, connected with the Springfield Hospital, was dedicated February 12. Dr. Chas. P. Hooker, Springfield, delivered an address on the late Dr. Frederick Wilcox Chapin, in whose memory the building was erected. The presentation address was delivered by Mr. George Dwight Pratt and the acceptance on behalf of the board by Col. Stanhope E. Blunt. The building was opened for general inspection February 13. The Chapin Memorial Building is the first of the six to be built facing the present Springfield Hospital group. It is a four-story rectangular building, fireproof, of most modern hospital construction. The first, second and third floors contain private rooms for forty-five patients, and on the fourth floor the Roentgen-ray department and operating rooms are located.

MICHIGAN

Board of Health a State Institution.—The supreme court on February 11 decided that the State Board of Health is not under the jurisdiction of the Civil Service Commission, thus affirming the decision of the circuit court in the case.

Personal.—Dr. Edward T. Abrams, Hancock, has been reappointed a member of the State Board of Health.——Dr. Athanase E. Gourdeau, Ishpeming, who has been under treatment in Chicago for several weeks, has returned home.——Dr. Daniel G. Cook, Holland, is under treatment in Rochester, Minn.——Dr. David B. Downing, Detroit, is ill with diphtheria in St. Mary's Hospital.——Dr. George T. Britton, Kalamazoo, is recovering from an operation for appendicitis.

Mayo in Michigan.—Dr. William J. Mayo, Rochester, Minn., was the guest of honor at the Detroit Academy of Medicine, February 23. On February 22, Dr. Mayo was the principal speaker at foundation day exercises of the department of medicine and surgery at the University of Michigan, Ann Arbor, and on February 24 the Kalamazoo Academy of Medicine gave a luncheon in honor of Dr. Mayo, after which he gave an address on "Some General Considerations Which Influence the Advisability of Surgical Treatment."

The Waters of Mt. Clemens.—Two hundred residents of Mt. Clemens, including twenty-four members of the Macombe County Medical Society, met at the annual banquet of the Mt. Clemens Business Association, February 25. The society has instituted a service between distant physicians and those residents of Mt. Clemens, whereby the local physician acts practically as the intern of the physician who sends the patient. The purpose of the society is to put the administration of baths under the direction of physicians so that scientific treatment may be assured.

MISSISSIPPI

Personal.—The office of Dr. Francis L. Furr, Barlow, was destroyed by fire, February 18.——Dr. Florence L. Dickerson, Salem, is reported to be seriously ill at her home as the result of a cerebral hemorrhage, February 14.——Fire at West Point, February 12, destroyed the offices of Drs. Byron H. Paslay, Samuel R. Deanes, F. Price Ivy and Lon W. Dotson.——The office of Chief of the Bureau of Vital Statistics, Bureau of Census, Washington, is said to have been offered to Dr. Waller S. Leathers, University, dean of the medical department of the University of Mississippi.

NEW YORK

Reappointed on Health Council.—Governor Whitman has reappointed Mr. Homer Folks, Yonkers, formerly secretary of the commission which made the investigation on which was passed the new health law, a member of the state public health council.

A New Antiquack Bill.—Senator George H. Whitney, at the instance of the State Department of Education, has introduced a bill into the legislature aimed at quack medicines and the physicians who lend their names and influence to the sale of such remedies. The bill defines as "unprofessional conduct" the advertising of services or remedies in any manner previously challenged by the State Board of Medical Examiners and disapproved by vote of the Board of Regents. The bill also regulates the issuance of licenses for the regents. Violation is made subject to criminal prosecution.

Personal.—Dr. John Van Duyn, Syracuse, was the guest of honor at a banquet in honor of his semicentennial of his entry into practice, given by the Onondaga County Medical Association and the Syracuse Academy of Medicine, February 23, at which more than 150 physicians paid tribute to the veteran of the profession.——Friends of Dr. Joseph S. Wheelwright, Southampton, gave him a dinner February 20, at which he was presented with a silver loving cup. Dr. Wheelwright sailed for France, February 27, to take charge of a hospital for the relief of war sufferers to be established near Paris.——Dr. Paul B. Brooks, Norwich, has been appointed district sanitary supervisor.

New York City

To Stop Crowding of Cars.—Steps were taken on February 26 by Health Commissioner Sigismund S. Goldwater, with the approval of the mayor, to stop overcrowding of the transit lines. The Public Service Commission having failed to remedy conditions which the Health Department has shown to be a menace to health and decency, the latter has acted by issuing mandatory orders on the New York Railways Company and the Belt Line Railway Corporation to stop overcrowding on the Fifty-Ninth and Eighty-Sixth Street crosstown lines. The number of passengers which it is permissible to carry is limited to one and one-half the seating capacity of the car. This order will be enforced by the police. Dr. Goldwater has signified his intention of taking up one line of transit after another until safe and sanitary conditions shall be secured.

NORTH CAROLINA

Two-County Health Officer.—Henderson and Vance counties have employed a whole-time health officer who commenced work January 1.

Personal.—Dr. Paul B. Means, Concord, has been appointed assistant physician to the New Jersey Hospital for Nervous Diseases, Skillman.——Dr. Arthur S. Pendleton, Raleigh, a member of the staff of the State Hospital, is ill with diphtheria.

NORTH DAKOTA

Personal.—Dr. William F. Maertz, Lidgerwood, has been appointed a member of the State Board of Medical Examiners, vice Dr. Frederick G. Benn, Kulm, resigned.——Dr. Louis W. Meckstroth, Wahpeton, announces his retirement from practice and that he will devote his time to the care of the estate of his sister.

Hospital News.—Governor Hanna suggests to the state legislature that efforts be made to induce the United States government to establish the proposed hospital for the treatment of tuberculosis among the Indians of North Dakota near the North Dakota State Tuberculosis Sanatorium, Dunseith, and not 15 miles east of it, as is at present contemplated. He advises that petition to this effect be sent to the government, as in his belief the two institutions, if located near each other, could cooperate and work in harmony to mutual advantage.——The new St. Alexius Hospital, Bismarck, was formally opened, February 15. The institution has four six-bed wards, besides sixty private rooms.

OHIO

Camp Renamed.—At a meeting of the directors of the Children's Fresh Air Camp of the Cleveland Federation of Charities and Philanthropy, February 16, eight additional directors were elected, and the name of the institution was changed to the Children's Fresh Air Camp and Hospital.

Personal.—The appointment of Dr. J. Morton Howell, Dayton, as a member of the State Board of Health, has been con-

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

ARKANSAS

College Gets Appropriation.—The Arkansas legislature has made an appropriation of $65,000 for the Medical Department of the University of Arkansas for the next biennium. It has also passed a bill providing for the erection of a state hospital at Little Rock to be conducted in connection with the medical department of the university.

GEORGIA

Medical Society Reorganized.—At a meeting of physicians of Mitchell County, held at Pelham, February 19, the Mitchell County Medical Association was reorganized and the first meeting will be held at Camilla on March 10.

Atlanta Neurologists Organize.—The Atlanta Neurological Society was organized February 11, with the following officers: president, Dr. E. Bates Block; vice-president, Dr. Hansell Crenshaw; secretary, Dr. Lewis M. Gaines. The society will hold its meetings on the second Thursday of each month.

Hospital Happenings.—A charter was granted on February 13 to the Cooperative Hospital Association, Atlanta. The organization has already leased a building in Atlanta for its work. The plan of the hospital is to furnish hospital treatment to persons who are unable to go into the pay wards of other hospitals.——The new university hospitals erected at Augusta at a cost of $500,000 have been turned over to the city by the contractors and the formal opening will occur about March 15.——A new site has been selected for the Georgia Baptist Hospital, Atlanta, and plans have been made for new buildings to accommodate about 500 patients. A new medical staff has also been selected.——The Hospital for Negroes, established by William H. Thomas at Rome is nearing completion. The ultimate plan of the hospital is to have cottages in addition for male and female patients, for a maternity hospital and for a hospital for children.

ILLINOIS

Hospital Dissolved.—The stockholders of the Amboy Hospital Company, at a recent meeting, voted to dissolve the corporation and on February 27 the building was sold at public auction.

State Board Will Provide Nitrate of Silver.—It is announced that the State Board of Health will shortly be ready to supply local physicians with silver nitrate in individual tubes for the avoidance of ophthalmia neonatorum.

Chicago

Personal.—Dr. Leigh K. Patton, an intern at Cook County Hospital, fell in an elevator shaft in the institution, February 24, fracturing his skull and right arm.—Drs. Greene V. Black, Truman W. Brophy and Eugene S. Talbot were awarded the degree of Doctor of Science at the dedicatory exercises of the Evans Museum and Dental Institute of the University of Pennsylvania, February 22.

INDIANA

Eugenics and Free Lunch Defeated.—The state legislature has defeated the eugenic bill, but has passed a bill to abolish the free-lunch counter in the saloons. The inspection made by the State Board of Health showed the free-lunch counter to be most insanitary.

Filtration Plant Ordered.—The public service commission has ordered the New Albany Water Company to install a filtration plant. The State Board of Health ordered this some time ago and was ignored by the city council, but after having evidence from Dr. John N. Hurty, Indianapolis, secretary of the State Board of Health, that samples of the Ohio River water showed typhoid bacillus, the order was issued.

Dental Clinic Appropriation.—The Indianapolis Board of Health has appropriated $500 to pay for material used in the work for schoolchildren at the dental clinics, and $300 has been appropriated for the use of spectacles for children who need them and whose parents cannot afford to buy them. The board has also signed a contract with the Indiana University School of Medicine under which, for the sum of $975 a month, the school agrees to maintain the city dispensary.

Child Welfare Exhibition.—During the week of February 16 to 25, a child welfare exhibit was held in Tomlinson Hall, Indianapolis, and was well attended. The exhibit was divided into numerous topics, among them being housing and homes, schools, moral and religious life, kindergarten, health, child labor and conservation of vision. A series of illustrated talks were given on the subject represented. In a central court there was a continuous program of drills, gymnastics and folk dances and four smaller courts were devoted to school work, domestic science, manual training, kindergarten, rural schools, and a model school room. The organization had for its head Dr. Frank B. Wynn, and the director of all the exhibit was Dr. W. F. King. Practically all the physicians of the city cooperated in making the exhibit a success. It is the intention to have the exhibit become a permanent one for use throughout the state.

Hurty Anniversary to Be Celebrated.—The Indianapolis Medical Society, at its meeting February 23, adopted a resolution suggesting a celebration March 12, to commemorate the nineteenth anniversary of Dr. John N. Hurty as state health officer. Dr. Frank B. Wynn, Indianapolis, president of the state society, and Drs. David Ross and Alfred Henry, president and secretary of the Indianapolis society, were named a committee to arrange a suitable observance of the anniversary.

During the past week Dr. Hurty was elected president of the Indiana Sanitary and Water Supply Association at its annual meeting. These justly deserved honors to Dr. Hurty are apropos, as the state legislature is now considering a bill which would make the state health officer a political appointee. The leading newspapers of the state have had scathing editorials denouncing this form of legislation.

IOWA

New Hospital Opened.—The *Primghar Hospital* was opened for inspection February 12 and 13; on February 14 dedicatory services were held, and the hospital was opened for the reception of patients on February 15.

Personal.—Dr. Campbell Palmer Howard, professor of medicine in the University of Iowa, Iowa City, has been granted an indefinite leave of absence and will leave for Montreal, February 27, to join the McGill General Overseas Hospital, Montreal, which will go to Europe next month. Dr. Clarence E. Van Epps will look after Dr. Howard's work in his absence.——Dr. M. Charles Mackin, assistant physician at the Clarinda State Hospital, has been appointed superintendent of the Iowa State Institution for Inebriates, Knoxville.——Dr. Joseph C. Ohlmacher, Clarinda, will succeed Dr. Mackin as first assistant physician at the Clarinda Hospital, and Dr. Roscoe D. Smith, third assistant physician, has been promoted to second assistant physician.——Dr. William S. Parks, Brighton, who has been operated on recently, has recovered and resumed practice.——Dr. George W. Yavorsky, Belle Plaine, has been appointed local surgeon for the North-Western System, vice Dr. James B. Cox, Belle Plaine, deceased.——Dr. Beth Vincent, Boston, has started for Europe to work in the American Ambulance Hospital, Paris.

KANSAS

Division of Fees.—A bill forbidding the secret division of physicians' fees has been introduced into the House of Representatives. It provides that no physician or surgeon shall pay or offer to pay to any other physician or surgeon any fee for patients brought to him for treatment nor receive any fee for sending patients to other physicians. Division of fees for professional services where made with the full knowledge of the patient or the person paying the bill is exempt. In a word, the bill is aimed at the secret division of fees between general practitioners and specialists, surgical or otherwise. A penalty of a fine of not more than $500 or imprisonment in the county jail for six months or both and the revocation of the licenses of the convicted persons is provided. Hospitals or clubs owning or operating hospitals are included within the provisions of the act which has been reported favorably by the house committee.

MARYLAND

Conference of Charities and Corrections.—The National Conference of Charities and Corrections will be held in Baltimore from May 12 to 19, inclusive.

Health Lectures for Negroes.—The Public Health Conference recently held proved so successful that it has been determined to hold a series of lectures on health topics for negroes exclusively.

MASSACHUSETTS

Summer School.—The Boston University School of Medicine announces that it will conduct a summer school for graduates in medicine from May 3 to June 12. Courses will be offered in dermatology, digestive diseases, gynecology, neurology, otology, obstetrics, orthopedics and pathology. Thirty-six members of the medical faculty will constitute the faculty of the summer school.

Personal.—Surg. Richard H. Creel, U. S. P. H. S., has declined the offer of Mayor Curley of Boston to make him head of the reorganized Boston Health Department, as the surgeon-general finds it impracticable to grant Surgeon Creel the necessary leave of absence.——Dr. John H. McCollom, Boston, for many years connected with the Boston City Hospital, retired February 15.——A banquet was tendered Dr. Herman C. Bumpus, the new president of Tufts College, by the medical and dental schools of the college, February 8. Dean Charles F. Painter, Boston, of the medical and dental schools was toastmaster.——Dr. George B. Magrath, Boston, has been reappointed medical examiner of Suffolk County.

Hospital Dedicated.—The Chapin Memorial Building, connected with the Springfield Hospital, was dedicated February 12. Dr. Chas. P. Hooker, Springfield, delivered an address on the late Dr. Frederick Wilcox Chapin, in whose memory the building was erected. The presentation address was delivered by Mr. George Dwight Pratt and the acceptance on behalf of the board by Col. Stanhope E. Blunt. The building was opened for general inspection February 13. The Chapin Memorial Building is the first of the six to be built facing the present Springfield Hospital group. It is a four-story rectangular building, fireproof, of most modern hospital construction. The first, second and third floors contain private rooms for forty-five patients, and on the fourth floor the Roentgen-ray department and operating rooms are located.

MICHIGAN

Board of Health a State Institution.—The supreme court on February 11 decided that the State Board of Health is *not under the jurisdiction of the Civil Service Commission*, thus affirming the decision of the circuit court in the case.

Personal.—Dr. Edward T. Abrams, Hancock, has been reappointed a member of the State Board of Health.——Dr. Athanase E. Gourdeau, Ishpeming, who has been under treatment in Chicago for several weeks, has returned home.——Dr. Daniel G. Cook, Holland, is under treatment in Rochester, Minn.——Dr. David B. Downing, Detroit, is ill with diphtheria in St. Mary's Hospital.——Dr. George T. Britton, Kalamazoo, is recovering from an operation for appendicitis.

Mayo in Michigan.—Dr. William J. Mayo, Rochester, Minn., was the guest of honor at the Detroit Academy of Medicine, February 23. On February 22, Dr. Mayo was the principal speaker at foundation day exercises of the department of medicine and surgery at the University of Michigan, Ann Arbor, and on February 24 the Kalamazoo Academy of Medicine gave a luncheon in honor of Dr. Mayo, after which he gave an address on "Some General Considerations Which Influence the Advisability of Surgical Treatment."

The Waters of Mt. Clemens.—Two hundred residents of Mt. Clemens, including twenty-four members of the Macombe County Medical Society, met at the annual banquet of the Mt. Clemens Business Association, February 25. The society has instituted a service between distant physicians and those residents of Mt. Dr. Wheelwright sailed for France, February 27, to take charge of a hospital for the relief of war sufferers to be established near Paris.——Dr. Paul B. Brooks, Norwich, has been appointed district sanitary supervisor.

New York City

To Stop Crowding of Cars.—Steps were taken on February 26 by Health Commissioner Sigismund S. Goldwater, with the approval of the mayor, to stop overcrowding of the transit lines. The Public Service Commission having failed to remedy conditions which the Health Department has shown to be a menace to health and decency, the latter has acted by issuing mandatory orders on the New York Railways Company and the Belt Line Railway Corporation to stop overcrowding on the Fifty-Ninth and Eighty-Sixth Street crosstown lines. The number of passengers which it is permissible to carry is limited to one and one-half the seating capacity of the car. This order will be enforced by the police. Dr. Goldwater has signified his intention of taking up one line of transit after another until safe and sanitary conditions shall be secured.

NORTH CAROLINA

Two-County Health Officer.—Henderson and Vance counties have employed a whole-time health officer who commenced work January 1.

Personal.—Dr. Paul B. Means, Concord, has been appointed assistant physician to the New Jersey Hospital for Nervous Diseases, Skillman.——Dr. Arthur S. Pendleton, Raleigh, a member of the staff of the State Hospital, is ill with diphtheria.

NORTH DAKOTA

Personal.—Dr. William F. Maertz, Lidgerwood, has been appointed a member of the State Board of Medical Examiners, vice Dr. Frederick G. Benn, Kulm, resigned.——Dr. Louis W. Meckstroth, Wahpeton, announces his retirement from practice and that he will devote his time to the care of the estate of his sister.

Hospital News.—Governor Hanna suggests to the state legislature that efforts be made to induce the United States government to establish the proposed hospital for the treatment of tuberculosis among the Indians of North Dakota near the North Dakota State Tuberculosis Sanatorium, Dunseith, and not 15 miles east of it, as is at present contemplated. He advises that petition to this effect be sent to the government, as in his belief the two institutions, if located near each other, could cooperate and work in harmony to mutual advantage.——The new St. Alexius Hospital, Bismarck, was formally opened, February 15. The institution has four six-bed wards, besides sixty private rooms.

OHIO

Camp Renamed.—At a meeting of the directors of the Children's Fresh Air Camp of the Cleveland Federation of Charities and Philanthropy, February 16, eight additional directors were elected, and the name of the institution was changed to the Children's Fresh Air Camp and Hospital.

Personal.—The appointment of Dr. J. Morton Howell, Dayton, as a member of the State Board of Health, has been confirmed by the senate.——Dr. W. H. H. Woland, Lindsey, is reported to be in a critical condition as the result of a cerebral hemorrhage.——Dr. George F. Zinninger, Canton, who was operated on in January at Rochester, Minn., has recovered and returned home. A reception was tendered him in his home, February 18, by the medical profession of the city, and Dr. Alonzo B. Walker, Canton, on behalf of the physicians, presented him with an office lamp.——Dr. Fred A. Cobb, Toledo, who has been seriously ill with erysipelas, is reported to be convalescent.——Dr. Henry J. Pool, Port Clinton, has lost the sight of one eye as the result of a gas explosion.

OKLAHOMA

Hospital Incorporated.—The Cushing Hospital Company has been incorporated with a capital stock of $4,000 and bids have been asked for a two story, twenty-five room brick hospital building.

Personal.—Dr. Powell Hayes, Frederick, has been appointed assistant physician at the Vinita State Hospital.——Dr. William G. Kiebler, Goltry, sustained a Colles fracture of the arm while cranking his automobile recently.——Dr. John W. Duke, Guthrie, has assumed the duties of state health commissioner, succeeding Dr. John C. Mahr, Shawnee.——Dr. George D. McLean, Oklahoma City, who recently underwent an operation for the removal of gall-stones, has fully recovered.

PENNSYLVANIA

Nurse Appointed for Exposition.—Miss Alice M. O'Halloran, chief nurse in State Department of Public Health, has been designated by Dr. S. G. Dixon, state health commissioner, to go to San Francisco to be in charge of the health department's exhibit in the state building.

Barbers Must Stand Medical Test.—The order recently issued by the Cresson Board of Health requiring all barbers to be sound physically, is rigidly enforced, and notices are being posted in Cresson announcing that all barbers will have to submit to medical examination. Milk dealers will have to submit health certificates and observe sanitary rules on their farms.

Personal.—Dr. Benjamin J. Millard, Mt. Carmel, who has been confined to the house on account of a fracture of the hip, is convalescent and has resumed practice at his office.——Dr. Clayton D. Fretz, Sellersville, has been appointed a member of the board of trustees of the Norristown State Hospital.——Dr. John F. Bryson, Girardville, was operated on recently at the Miner's Hospital, Pottsville, and is doing well.——Dr. John B. Cressinger, Sunbury, who has been ill with pneumonia, is convalescent.

Philadelphia

Patent Medicine Destroyed.—More than 4,000 bottles of "Father John's" medicine, siezed by the government of this city in 1912 on a charge that they were misbranded and misled the public, were condemned and ordered destroyed, February 18, under a decree filed in the United States district court.

Nation-Wide Sanitation Campaign Advocated.—Prof. Charles Wardell Stiles of the Rockefeller Foundation delivered the ninth Weir Mitchell lecture at the College of Physicians, February 16, in which he advocated a nation-wide campaign for sanitation as the only means of stamping out communicable diseases.

Midwinter Smoker.—The midwinter smoker of the Alumni Association of Jefferson Medical College was held in the roof garden of the Hotel Adelphia, March 4. Dr. William W. Keen, emeritus professor of surgery at the college, gave an informal talk on "The Contrast Between the Surgery of the Civil War and that of the Present War."

New System in Health Crusade.—Three hundred bulletin boards, to furnish health information to the most congested housing districts of the city, will be erected in courts and alleys by the child federation. Health talks prepared by the new federation council will be printed in English, Italian, Yiddish, German, Hungarian and many other languages required by the various neighborhoods.

Postgraduate Clinics.—The course of postgraduate clinics on the heart and lungs given Friday afternoon, 5 to 6 o'clock, in the amphitheater of Philadelphia General Hospital, include the following for March 5: Tricuspid and pulmonary-valve lesions; relation of the heart and lungs in disease; March 12, angina pectoris, true and false; March 19, heart block and Stokes-Adams syndrome, and March 26, cardiac neurosis (so called). Physicians are cordially invited to participate.

Personal.—The house of Dr. Nathan Blumberg was destroyed by fire, February 20.——Dr. George H. Shuman has resigned from the department of health and charities to engage in private practice.——Dr. Aaron Brav has been appointed ophthalmologist to the Jewish Hospital to fill the position left vacant by the recent death of Dr. Isaac Leopold.——Dr. Robert R. Bensley of the University of Chicago will deliver the tenth Rush Society lecture of the University of Pennsylvania, March 10.

University of Pennsylvania Alumni.—The Philadelphia Alumni Society of the medical department, University of Pennsylvania, at the annual meeting, voted to increase the Dr. Roland G. Curtin Scholarship Memorial Fund with $250 of last year's surplus. The annual election of officers resulted as follows: president, Dr. William D. Robinson; honorary vice-president, Dr. E. F. Smith; vice-presidents, Drs. Howard A. Sutton, William F. Guilfoyle and James A. Kelly; corresponding secretary, Dr. Benjamin F. Stahl; recording secretary, Dr. J. Milton Griscom, and treasurer, Dr. Morris Booth Miller.

TEXAS

Plague Appropriation Measure Killed.—The Clark bill appropriating $25,000 for the use of the state health officer in the prevention of the entrance of plague into the state, was defeated in the state senate after having passed to engrossment.

Vaccinations at Laredo.—On account of the epidemic of smallpox at Nuevo Laredo, Mexico, February 21, the physicians in the immigration service at Laredo, Texas, compelled the vaccination of every person coming into the United States from the Mexican side. Many persons came over to celebrate Washington's birthday and some thousands attended the bull fight in the Mexican town. On their entrance into the state all were vaccinated.

Personal.—Dr. Casper R. Byars, Bay City, has been appointed health officer of Matagorda County.——Dr. John E. McClung, Corsicana, has been appointed specialist on diseases of the eye, ear, nose and throat at the State Orphan Home.——Dr. Edgar L. Gilcreest, Gainesville, left for Washington, February 14, to report for duty at the headquarters of the American National Red Cross. He will be stationed at the American Hospital, Paignton.——Dr. Thomas B. Bass has been reelected superintendent of the State Epileptic Colony, Abilene.

County Society to Build Bungalow.—The proposition to erect a building exclusively for officers of the Bexar County, San Antonio, Medical Society, and another proposition to lease offices together in an office building having been rejected by the organization, the committee on the general project of quarters for the organization and joint offices for members, have reported in favor of the construction of a one-story fireproof building, of bungalow type, giving a spacious meeting hall, 30 by 44, a pathological museum and a smoking hall, and their report was unanimously adopted. The building, as proposed, will cost about $20,000.

CANADA

Clearing Hospital from Quebec.—The Canadian militia department has sanctioned the formation of a French-Canadian casualty clearing hospital in connection with the army medical corps for overseas service. It will consist of one lieutenant colonel, two majors, one quartermaster, two junior officers, nine surgeons, seven corporals, and fifty rank and file. There will be no nurses. The hospital is being organized under the auspices of Laval University.

Reciprocity with Great Britain.—The Ontario legislature, now in session, is considering a measure to provide for reciprocity between the Ontario Medical Council and the Medical Council of Great Britain. When this measure (and there appears to be no opposition to it) is passed, the Ontario practitioners who are volunteering for the war will be enabled to practice in the hospitals and have charge of the hospitals it is proposed to equip and send across the Atlantic in the near future.

University News.—If the 1,800 students of the University of Toronto, who are at present in training go to the front, the university will be seriously handicapped. Their fees for a year would amount to $151,000, which will be lost to the institution. There would be still left 2,700 students out of the present total of 4,500. Last year's deficit amounted to $87,000.

The medical department will suffer most severely. It is understood that the entire staff, to the number of ninety, has volunteered, but it is not likely that all will be accepted.

Personal.—Dr. Andrew Croll, Saskatoon, has been accepted on the staff of the General Hospital with the Second Canadian expeditionary force.——Dr. Mary E. Crawford, Winnipeg, has been elected president of the Political Equality League.——Lieut.-Col. John Taylor Fotheringham, M.D., Toronto, has been appointed chief of the medical staff of the Second Canadian Overseas Force.——Surg.-Gen. Carleton Jones, director of the Canadian Army Medical Service, who is in England with the First Contingent, has left for France to establish a clearing hospital so that all Canadian wounded may be sent to the Duchess of Connaught Hospital at Cliveden, in Buckinghamshire.

GENERAL

Leprosarium Bill Passed by House.—A bill to authorize the establishment of a home for lepers under the United States Public Health Service was passed by the House of Representatives, February 25, and sent to the Senate.

Tri-State Physicians Meet.—The seventeenth annual session of the Tri-State Medical Society of the Carolinas and Virginia was held in Charleston, S. C., February 17 and 18 under the presidency of Dr. Edward C. Register, Charlotte, N. C., and the following officers were elected: president, Dr. James H. McIntosh, Columbia, S. C.; vice-presidents, Drs. Gottlob A. Neuffer, Abbeville, S. C.; Carl V. Reynolds, Asheville. N. C.; and Beverley R. Tucker, Richmond, Va.; and secretary-treasurer, Dr. Rolfe E. Hughes (reelected), Laurens, S. C.

Service May Not Have Expert Engineer.—Controller Downey of the Treasury has ruled that the office of sanitary expert engineer for the Public Health Service may not be created nor salary paid under the existing law. The cause of this action was the opinion expressed by Surgeon-General Blue that such expert assistants were needed in the prevention of interstate spread of diseases, including typhoid fever and bubonic plague. General Blue also indicated that many states and municipalities are willing to undertake work for the eradication of disease liable to interstate spread, provided they can receive experts' advice from the Public Health Service, and this advice only a sanitary engineer would be qualified to give.

Bequests and Donations.—The following bequests and donations have recently been announced:

Home for Destitute Crippled Children and Mary Thompson Hospital for Women and Children, Chicago, each $100,000 by the will of Alexander A. McKay.

Columbia University, for research in the cause, prevention and cure of cancer, $100,000; Hebrew Orphan Asylum, New York City, Stoney Wold Sanatorium, Loomis Sanatorium and New York Skin and Cancer Hospital, each $10,000; Mt. Sinai Hospital, New York City, $20,000, one-half of which is for the dedication of two beds in memory of the testator's parents; Presbyterian Hospital, $5,000, and also $7,500 for the endowment of a bed in memory of Margaret Carson Rowan; St. Luke's Hospital, Montefiore Home, and Hospital Saturday and Sunday Association, $5,000; German Hospital and Crippled Children's East Side Free School, New York City, each $2,500, by the will of Emil C. Bondy, New York City.

National Committee on Mental Hygiene, a donation of $44,500 by Mrs. Elizabeth Milbank Anderson and one of $40,000 by Mrs. William K. Vanderbilt.

Rockefeller Foundation, an appropriation to retain the services of medical director Dr. Thomas W. Salmon, for three years.

New York Foundling Hospital, $2,000 by the will of Rosanna M. Nagle.

Howard Hospital, Philadelphia, $5,000 to establish a free bed to be known as the Annie E. Ulmer bed to be devoted to the use of female patients.

Philadelphia Hospital for Women, $1,000 by the will of Annie E. Matthew.

Presbyterian Hospital, Philadelphia, $5,000 by the will of Anna E. Teal.

Germantown Hospital, $5,000 by the will of Louisa C. Rodney.

FOREIGN

Statue of Florence Nightingale.—The cable brings word that a statue of Florence Nightingale was unveiled at London, February 24. It is the first instance in which a statue of a woman, aside from royalty, has been erected publicly in London. The figure bears a lamp in the right hand. It forms a part of the Crimean memorial group in Waterloo place, the cost of which was provided for by small subscriptions.

Orthopedic Hospital and Training School Inaugurated at Vienna.—Prof. H. Spitzy is at the head of this new institution for cripples, which comprises a dispensary, a hospital and a training school, each in a separate building, formerly a school building. There are beds for 1,000, and 600 are already filled. The training school has facilities for teaching twenty-one trades, and arrangements are already under way to enlarge its quarters.

Deaths in the Profession Abroad.—L. Laquer, a leading neurologist and medicolegal expert, died at Frankfurt a.M., aged 57. His works on feeble-minded children, kleptomania and electrotherapy of nerves are particularly well known.——J. Arnold, professor of pathologic anatomy at the University of Heidelberg, died recently, aged 79. Among the special subjects studied by him were inhalation of dust and the anatomy of the eye in the embryo.——Prof. Robert von Olshausen, the senior member of the medical faculty of the University of Berlin and honorary president of the national society of obstetricians and gynecologists, died February 2, aged 80. He was one of the leaders in modern gynecology and its publications.

WAR NOTES

Death of Dr. Kara.—Dr. John M. Kara, one of the three physicians in the Bohemian-American Red Cross unit sent to Servia, died recently of typhus fever. He was a native of Chicago, a graduate of the University of Illinois Medical Department in 1910.

Belgian Field Hospitals Need Aid.—The wife of Antoine Depage, the famous surgeon of Belgium, is visiting in America as the personal representative of the king and queen of Belgium, to seek financial and other aid for the field hospitals of the Belgian Red Cross. There is a woful lack of ambulances and field hospital appliances and personnel, and the wounded have suffered terribly from the lack of proper accommodations.

Disease Carriers Found.—Lieut.-Col. John T. Fotheringham, Toronto, chief surgeon of the Second Canadian Expeditionary Force, has discovered five meningitis carriers among the members of one of the kitchen fatigues, although the carriers themselves were not suffering from the disease. To further minimize the danger of the disease, Colonel Fotheringham has ordered 2,000 doses of meningitis prophylactic serum to immunize the men against the disease. There have been eight cases of meningitis thus far at the exhibition camp, with one death.

Medical Committee on Food for the Populace in Germany.—Kirchner is at the head of a committee, mainly of physicians, appointed to educate the public in economy of foodstuffs. Addresses and demonstrations are to be held, medical men teaching the principles of rational diet, and trained cooks giving demonstrations in the school buildings. Pamphlets and circulars are also being published to aid in the campaign for economy. The committee includes also representatives from national women's organizations, insurance societies and others.

Nostrums and the War.—The German authorities have been constrained to issue a warning against certain donations to the troops which the heedless buy, on the manufacturers' claims, to send to friends at the front. One article in particular is specified, "the so-called Microcid Tablets, manufactured for our soldiers in the field" and claimed to be a "sure protection against cholera, typhus, dysentery, etc., as it clears the water of germs in two minutes." A warning is also issued against certain portable filters that are advertised as suitable gifts for the men in the trenches. "Another article in regard to which a warning has been issued, is Eusitin, which is alleged to keep up the strength when food is not available. This marvellous action is ascribed to the content of 0.2 gm. dry extract of mallow in each box."

Red Cross Activities.—Several large shipments of hospital supplies and clothing have been started across the Atlantic by the American Red Cross in the last few days. Thirteen of the seventeen light motor ambulances contributed by Yale and Harvard universities have been shipped and the remainder will be sent very shortly. Of these, four each are consigned to the French, German, Austro-Hungarian and British Red Cross and one ambulance is to go to the Belgian Red Cross.——To the British Red Cross, 2,000 pounds of chloroform, 15 bales of blankets and 11,000 pounds of absorbent cotton have been sent.——Two consignments of hospital and miscellaneous non-combatant relief supplies were sent to France by the American Red Cross on the steamer *Rochambeau*. One of these shipments consists of 255 boxes including 9 cases of tetanus, typhoid and diphtheria antitoxin and is consigned to the American Relief Clearing House in Paris and the second consignment is addressed to Dr. Robert Fitch, in charge of a large military hospital in Yvetot, France.——The American Red Cross has also delivered to the Russian-American line in New York for shipment on the steamer *Kursk* as soon as navigation opens, 150 cases of hospital and non-combatant relief supplies for Poland, addressed to Warsaw, 189 cases of medical and surgical supplies for the Russian Red Cross at Petrograd and 40 cases for the American Hospital, Petrograd, which has been fitted out by the American Red Cross.——The Mayor of Pau, where two American Red Cross units have been stationed for several months, pays eloquent tribute to the work of the surgeons and nurses attached to the units and extends to the American Red Cross the official expression of the gratitude of the municipal authorities of Pau, the wounded and of the medical fraternity of the city.

Aid for Belgian Physicians.—It will be noticed that six instances are mentioned below and others have been published of the interest of medical societies in this cause. This should be encouraged. There are thousands of physicians who would gladly give a small sum—say a dollar or two—all they can afford, but who do not feel like sending such a small amount, and therefore send none. We suggest that officers of county societies consider whether they cannot aid in this humanitarian work.—The report of the treasurer of the committee of American physicians for the aid of the Belgian profession for the week ending Feb. 27, 1915, lists the following contributions:

The Monmouth Medical Club, Monmouth, Ill.	$ 10.00
The Adams Co. Med. Soc., Quincy, Ill.	42.00
Dr. Charles H. Smith, Uniontown, Pa.	25.00
Dr. Frederick J. Walter, Daytona, Fla.	10.00
Dr. Austin C. Brant, Canton, Ohio	5.00
Dr. William D. Byrne, Chicago, Ill.	5.00
Dr. Simon Levin, Lake Linden, Mich.	5.00
Dr. Miles F. Porter, Fort Wayne, Ind.	5.00
Dr. Joseph L. Duncan, Pittsburgh, Pa.	10.00
Dr. James M. Patton, Vandergrift, Pa.	1.00
Dr. Neri B. Williams, Perkasie, Pa.	1.00
Dr. Wilson F. Phillips, Dorchester, Mass.	5.00
Dr. Donald C. Balfour, Rochester, Minn.	25.00
Dr. Austin Flint, Jr., New York, N. Y.	25.00
Dr. Evan T. Steadman, Hoboken, N. J.	10.00
Dr. John B. Nichols, Washington, D. C.	10.00
Dr. Hermann G. Klotz, New York, N. Y.	5.00
Dr. George P. Coopernail, Bedford, N. Y.	5.00
Dr. Kay I. Sanes, Pittsburgh, Pa.	25.00
Dr. Herman F. Vickery, Boston, Mass.	25.00
Dr. Henry H. Atkinson, Fordyce, Ark.	5.00
Dr. Archibald MacLaren, St Paul, Minn.	25.00
Dr. Helen G. Putnam, Providence, R. I.	5.00
Maricopa Co. Med. Soc., Phoenix, Ariz.	25.00
Dr. John D. S. Davis, Birmingham, Ala.	5.00
Dr. James M. Popp, New Castle, Pa.	5.00
Dr. Horace Binney, Boston, Mass.	5.00
Dr. Warren Wilson, Northfield Minn.	5.00
Dr. Gibbs Biscoe, Pendleton, Ark.	5.00
Dr. Eleanore F. Boulton, Philadelphia, Pa.	5.00
Dr. Orr L. Perry, Elkins, W. Va.	2.00
Dr. John P. Getter, Belleville, Pa.	2.00
Dr. W. H. Witt, Nashville, Tenn.	5.00
Salt Lake Co. Med. Soc., Salt Lake City, Utah	50.00
New York Medical Union, New York, N. Y.	100.00
The Montgomery Co. Med. Soc., Dayton, Ohio	304.50

Receipts for week ending February 27		$ 807.50
Previously reported receipts		3,579.00
Total receipts		$4,386.50
Previously reported disbursements	$3,575.00	
Disbursements for week ending February 27, 352 boxes of food at $2.30	809.60	
Total disbursements		$4,384.60
Balance		$ 1.90

LONDON LETTER

London, Feb. 11, 1915.

The War

THE PREVENTION OF DISEASE

This is the first war in which we have had an organized sanitary service. It was established some years ago and has gradually been perfected. The importance of disease in war is shown by the fact that in our Napoleonic wars only 3 per cent. of the deaths were due to wounds, 97 per cent. being due to disease. So far the amount of illness has been very small. The greater part has been due to wet and cold, which is easily explained by the long hours in wet trenches. The army medical department has issued a small leaflet to officers explaining the steps that should be taken to prevent frostbite. This condition is three times as common among the men as the officers, and is presumably due to the fact that the latter have better boots, leggings and equipments generally. Cases of typhoid fever are very rare and have occurred almost entirely among the uninoculated. Hence opinion in favor of making inoculation compulsory is growing, and Lord Kitchener has gone so far as to curtail the leave of men who are uninoculated. Of course an outcry has been made by the antivaccinationists and antivivisectionists against what they call the "terrorizing" of men who object to inoculation. Speaking in Parliament on behalf of the government, in reply to these cranks, Dr. Addison pointed out that whereas in the South African war when inoculation was in its infancy we had 58,000 cases of typhoid fever, we have had only 421 up to the present in this war.

THE SCARCITY OF SYNTHETIC DRUGS

As stated in previous letters, a beginning has been made in manufacturing some of the more important synthetic drugs for which in the past we have been almost entirely dependent on Germany. At the same time attention has been called to the fact that we are perhaps far better without the enormous and constantly increasing number of synthetic drugs which Germany produces. At the Pharmaceutical Society, Mr. C. A. Hill read a paper in which he said that if a German chemical factory is producing on a large scale a certain chemical compound, and in the manufacture of that compound a by-product is obtained for which there is no obvious outlet, the research staff and ancillary to that laboratory factory sets to work to find an outlet. The by-product may be put on the market and boomed as such, or it may serve as the raw material for the preparation of some other substance. In the *British Medical Journal*, reference is made to a recent meeting of the Newcastle Section of the Society of Chemical Industry. Mr. N. H. Martin expressed the opinion that the success of certain synthetic drugs, such as antipyrin, was responsible for the lowering of the scientific value of German chemical work in recent years, and quoted the following passage from an address he delivered in 1899: "Hardly a month passes but that some new substitution compound with a trivial name to indicate its alleged medicinal properties, and a scientific name intended to suggest profound research, is introduced to English medicine. They come with laboratory and medical reports attested by men with university degrees, couched in language calculated to deceive the very elect, but the touchstone of practical trial reveals how science has been prostituted to commercial ends, and the substances one after the other, passed to oblivion."

THE INCREASED COST OF FOOD

In Parliament a motion regretting the rise in price of the necessaries of life, and calling on the government to endeavor to prevent this consequence of war, was brought forward by a labor member. The premier, Mr. Asquith, in reply pointed out that the rise was substantially below the level which the most sober-minded and best-informed judgments in the country would have apprehended or anticipated from a war involving almost the whole civilized world. Moreover, the level of prices does not exceed and in many respects falls short of the level which most of those who were now living have experienced in times of peace. Taking the four necessaries of life, wheat is now 72 per cent. higher than at the corresponding time last year; British meat, 6 per cent.; foreign meat, 12 per cent.; sugar, 72 per cent. (but as the price was abnormally low last year the increase is only 43 per cent. on the average of the last three years); and coal, 15 per cent. From 1871 to 1875, after the conclusion of the Franco-German war, with the exception of coal, everything in this list was dearer than it is now, and even up to 1885 prices were no higher than they are now. On the other hand, money wages were from 15 to 20 per cent. lower than they are now. Further, as a result of the war there has not been so much anticipated widespread unemployment. The large expenditure of the government in various branches of industry, and the liberal allowances to the wives of men who are fighting, have enabled the working classes to consume nearly on the same scale as before the war. The rise in the price of wheat is due to two causes—diminished supply and increased demand. The former is not entirely due to the war. There has been a failure of the Australian crop, and the high prices in India have led to a temporary embargo on the export of wheat. The Argentine crop, owing to bad weather, is three weeks late in going to the coast. By the closing of the Dardanelles, the war has cut off the Russian crop. The depredation of crops in Belgium and Northern France and the greatly reduced production in the Balkans are other causes. Increased consumption is due to the fact that men in the armies eat more than they did in civil life. Another cause of the rise is an increase of freights and speculation in the Chicago and New York markets. According to the premier, no army in the world has ever been so well fed as the British army operating in France, and in no respect has it been better supplied than with meat. The government in the earliest stages of the war purchased on a large scale the available stocks of sugar in the world, and now has sufficient to last many months, and the price of sugar in this country is approximately the same as in the United States. Our policy has prevented purchase by this country directly or indirectly of enemy sugar, and restricted the sale by Germany and Austria of their surplus stocks. The rise in the price of coal is partly due to increased freights, and partly to a diminished volume of labor available in the mines in consequence of enlistment. There is also a shortage of transport labor and seamen in consequence of enlistment and the removal of enemy aliens from our shipping service. The government is doing everything possible to facilitate transport. There is, of course, a shortage of shipping because of the disappearance from the ocean of the whole of the merchant service of Germany and Austria, and also because the Admiralty is employing for war transport a fifth of the British tonnage. To the disappointment of the Labor Party, Mr. Asquith declined to take any steps for fixing maximum prices. Speaking not as "an old-fashioned political economist" but as a practical man, he did not believe in such steps. In Germany they had the most disastrous consequences.

VOLUNTARY HOSPITALS AND WOUNDED SOLDIERS

The Council of the British Hospitals Association, 14 Victoria Street, Westminster, has been considering the varying conditions under which the voluntary hospitals are receiving wounded soldiers for treatment. Arrangements which the War Office has made as to payment vary considerably; for instance, few, if any, of the hospitals in London have asked for any payment from the government, while most of the provincial hospitals expect to be paid at rates which vary from 50 cents to $1 per patient per day. It is proposed to apply to the War Office to establish a uniform scale of payment with all the voluntary hospitals.

The Danger of Prescribing Over the Telephone

An unfortunate mistake illustrates the danger of prescribing poisonous drugs over the telephone. A man was in a nursing home preliminary to operation. His physician telephoned to a dispenser whom he employed to prepare a solution for hypodermic injection containing one seventy-fifth grain of physostigmin (eserin) sulphate. The dispenser mistook the direction and prepared a solution containing 0.75 grain (sixty times too much). Soon afterward he discovered his mistake and communicated with the physician, who telephoned to the nursing home too late to prevent the administration. He directed an antidote to be given and motored to the home only to find the patient dying. There is one consolation in the case: the patient was suffering from a malignant disease.

PARIS LETTER

Paris, Feb. 11, 1915.

The War

FROZEN FEET IN THE ARMY

The number of men sent from the front to the hospitals with the diagnosis of frozen feet is continually increasing. Lesions of all degrees, varying from simple blisters to total gangrene of the toes or even of the entire foot, are seen. This seems rather surprising since during this winter the temperature in our country has rarely fallen below zero C. According to Dr. Témoin of Bourges, who has made an interesting report on this subject to the Académie de médecine, many of the cases are not really cases of freezing, being produced less by the action of the cold than by the constriction of the feet in a shoe that is too tight, aided by the impairment of the circulation of the leg produced by the bands around the calves worn by many of our soldiers. Dampness aggravates the condition, producing a maceration of the tissues of the foot and making the shoes shrink still more. The low temperature favors vasoconstriction and the circulation becomes constantly slower. In support of this view, Témoin cites the example of the Russian and German troops who wear loose, waterproof boots and among whom, although they fight under the same conditions as our soldiers, frozen feet are not prevalent.

The result, to be sure, is the same whether the foot is frozen or the circulation stops, but practically the distinction is important. While one cannot prevent the effects of freezing, which is generally produced rapidly, it is not so with respect to constriction of the leg and the foot, the effects of which are produced slowly. None of the men hitherto sent to the hospitals after the diagnosis of frozen feet had been affected before the fourth day of sojourn in the water. The preventive remedy consists in the elimination of the band around the calf, loosening the lacings of the shoe and the employment of greasy material—oiled paper or greased socks—to cover the foot all over during the combatants' stay in trenches filled with water.

Témoin mentions a chief of service who, by merely telling his men in the trench to take off their shoes twice a day for a quarter of an hour, lowered the proportion of frozen feet. The academy agreed with Dr. Témoin's findings and voted unanimously to transmit his paper to the minister of war.

Dr. J. A. Sicard, agrégé professor at the Faculté de médecine de Paris, read a paper on the same subject before the Société médicale des hôpitaux de Paris. Having had the opportunity of observing a large number of cases of frozen feet, he remarked that the left foot was more frequently affected than the right. He attributed this circumstance to the fact that, whether seated or standing, right-handed persons, who are in the immense majority, automatically and unconsciously make more numerous and more extensive movements with the right foot than with the left. As predisposing causes besides the bands around the calves, Sicard mentions plantar hyperidrosis, chilblains of the toes and varicose condition of the legs.

As a prophylactic measure, Sicard recommends protecting the sock itself from contact with the cold by wrapping it with wool, etc. Greasing the foot coverings liberally also gives good results; likewise the interposition of strips of paper between the socks and the skin. As a palliative treatment, Sicard recommends the use of a mixture of 80 c.c. of alcohol 70°, 20 c.c. of ordinary glycerin and 1 c.c. of tincture of iodin. Gauze wet with this mixture is placed on the affected portions and covered with wadding lightly tied in place.

THE SOLDIERS' RATION OF FOOD IN WAR TIME

At one of the last sessions of the Académie des sciences, Dr. Armand Gautier, professor of chemistry at the Faculté de médecine de Paris, reported some interesting details in regard to the work of the committee instituted by the minister of war in 1907, for the study of soldiers' rations. As a standard for comparison, the committee took the normal ration of a laborer at hard manual work. After numerous investigations it was recognized that in a moderate climate, a quantity of food sufficient for the development of 4,133 calories was necessary per capita per day. In cold climates like that of Russia, 100 calories more should be added. The present food ration is equivalent only to 3,189 calories. During peace and even at the outbreak of the war, there was nothing alarming in the situation. Later the deficiency has been partly made up by adding to the ordinary ration of the troops 100 gm. of bread, 24 gm. of coffee, 30 gm. of sugar and 10 gm. of fat. This amounts to 3,900 calories. Dr. Gautier concludes that to obtain the number of calories corresponding to the ideal alimentary regimen, it would be necessary to supplement the ration further by 30 gm. of fat, 150 of bread and 50 centiliters of wine.

THE USE OF OATS FOR HUMAN FOOD

At the time of mobilization of the army, Captain Moreau submitted to the military authorities and to the central farmers' organization of France an important work on this subject which has become of special interest through later events. In comparison with barley and rye, oats have a superior nutritive value, as shown by the following figures:

	Oats	Rye	Barley
Protein	12.68	7.52 to 9.91	7.98 to 13.27
Fat	5.90	1.04 to 1.36	1.28 to 2.20

This shows the superiority of oats over the cereals ordinarily employed in France. Captain Moreau recommends using oats in the form of porridge. An officer has succeeded in preparing an oat biscuit which is easily transportable and much superior in flavor to the ordinary war bread. It is of considerable nutritive value. Experiments were made on groups of twenty soldiers undergoing particularly hard training. In each case there was considerable increase of weight and muscular force. It has therefore been decided to regard the oat crops in invested places as food material for human beings.

A MISSION OF THE JAPANESE RED CROSS TO PARIS

A mission of the Japanese Red Cross which left Yokohama December 16, last, has arrived in Paris. It is headed by Dr. H. Shiota, includes thirty-one persons and is accompanied by fourteen carloads of supplies, amounting to between 130 and 140 tons. Other missions have already been sent by the Japanese Red Cross into England and Russia, respectively.

Personal

During the session of February 2, the Académie de médecine elected as associate member Prince Albert of Monaco, who is already a member of the Académie des sciences. The Prince of Monaco has given much encouragement to medical and physiologic studies, apart from his personal work in oceanography in which physiologic applications have had a large share. At the preceding session, the academy unanimously elected Dr. Laurent of Brussels as foreign correspondent.

BERLIN LETTER

Berlin, Feb. 2, 1915.

The War

CONSERVATION OF THE FOOD SUPPLY

The newest regulation of our government concerning our nutritional condition requires a seizure of all grain and flour, and provides that communities shall arrange to distribute each week a limited ration of bread and flour to each citizen. Altogether, 2 kilograms of bread and flour per capita per week are permitted. The previous conditions with reference to the composition of white bread and rye bread remain undisturbed. That the population can easily abide by this restriction is evident, for no one has need of more than 2 kilograms of bread and flour and other flour products. Even if such a limitation may not be easy for those accustomed to luxury and fond of pastry, they will very soon accustom themselves to it. The matter of chief importance is that in this way, without doubt, the present stores of cereals will last until the next harvest, and in this way the starvation plan of England will be foiled. The leading English papers admit this to be their plan, at the same time taking the opportunity to pronounce high praises on the remarkable capacity of the German people for organization.

THE WOUNDED

Since our offensive has diminished in the west, especially in Flanders, and probably also on account of greater prudence in the attacks, the number of the wounded among our soldiers has grown less. Letters have been received in the last few weeks from six different places on the western front in which physicians speak of the lack of work. Naturally, not the slightest sympathy can exist for these unemployed physicians.

THE EXPOSITION ON THE CARE OF THE WOUNDED

In the exposition on the care of the wounded and sick which has had a very large attendance and for that reason has completely fulfilled its purpose, interesting lectures have been delivered by various physicians. Among others, Holländer of Berlin, professor of medical history, gave a lecture on the history of sanitation.

A HISTORY OF THE CARE OF THE WOUNDED IN WAR

Holländer said that in prehistoric times it is unlikely that there was a medical service. The lower class of medical servants practiced surgery, while for the treatment of diseases sent by the gods, a class of priests developed who enriched themselves by traffic in amulets in addition to profit derived from the sacrifices for the deities. In early antiquity, as can be seen from the Iliad and the Odyssey, the treatment of the wounded depended on the help of comrades. There was a great mortality from wounds. In the Old Testament surgical treatment on the field of battle is not indicated. The Greek soldiers, after a battle, hastened to the shrines of Aesculapius. Up to the decline of ancient civilization, the life of the individual was esteemed of little value, and hence arose an inferior conception of the medical profession. The Romans regarded it as a sordid business and left it to slaves and women. In the year 219 B. C., the first Greek surgeon came to Rome, and it is first among the Caesars that we find systematic military medical service. Still the soldiers gladly permitted themselves to be treated in the temple of the god of healing, Aesculapius, whose popularity, according to a polemic article of Origen, raised the question whether Christ or Aesculapius was the real god of healing. Hospitals are only occasionally noted in the history of antiquity. Thus it is said in the Bible that the leprous king, Uzzia, spent the rest of his life in a hospital. We know of a military hospital in the times of the Roman Caesars through excavations at Neuss which, like archeology in general, with its excavations of medical votive tablets and instruments, gives us better ideas of the medical military service than the statements of authors. The German people had those wounded in battle treated by their wives, who remained in their city of wagons behind the line of battle. Charms, especially mandrake root, played a great rôle. In the early middle ages, the women of the castle, skilled in the healing art, took up the care of the wounded in the battles of the Guelphs and the Hohenstaufen. The need of surgeons was first markedly felt when great armies like those of the Crusades were brought together so that epidemics, wounds and hunger left only 50,000 out of the 750,000 men of Gottfried von Bouillon to reach Jerusalem. This lack led the Crusaders to help themselves by founding orders of knights for the care of the wounded and sick. Indeed, Richard the Lion Hearted had a hospital ship accompany his troops to the coast of Palestine. At this time, also, the advance of medicine began in the University of Salerno, where distinguished surgeons were employed whose writings we know and whose methods are exhibited in pictures from their works; but it was the development of anatomy under Vesalius, whose fourth centenary was celebrated a short time ago, and the introduction of firearms that brought about an advance in military surgery. Three questions interested the surgeons in those times: the extraction of bullets, the poisoning of wounds from the gases from powder, and the checking of hemorrhage, which Ambroise Paré solved by tying the vessels. The establishment of an organized military medical service occurred first with the introduction of standing armies. Under King Frederick I of Prussia, the Charité Hospital was erected as the first garrison hospital and the medical college was established, and in 1795 the Pepiniere (nursery, professional school), which is now the Kaiser Wilhelm's Academy for the Education of Army Surgeons, was established.

WAR AND THE POPULATION

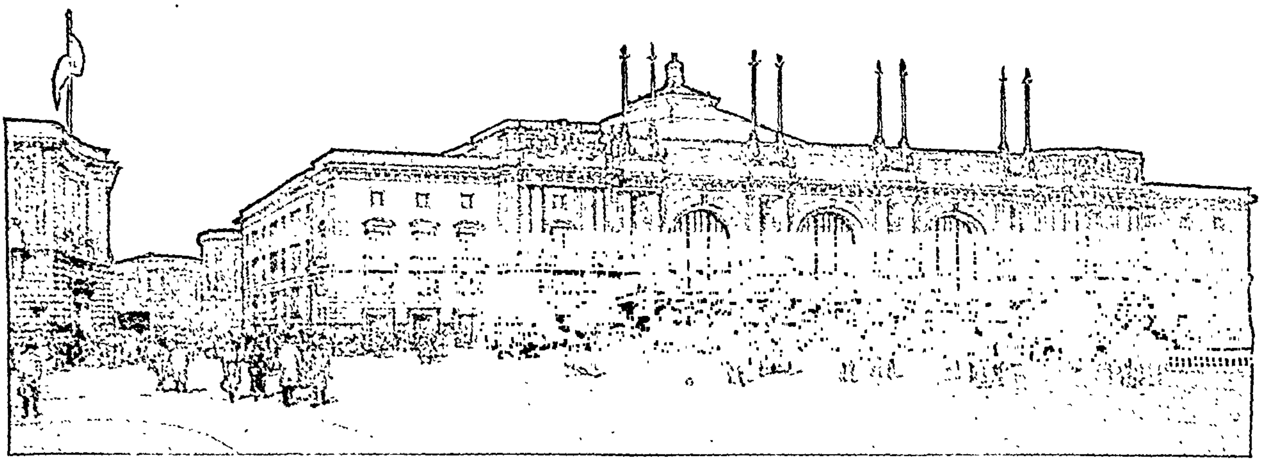
Professor Schwiening, surgical historian, reporter of the war office, and associate editor of the *Deutsche medizinische Wochenschrift*, recently spoke of the influence of the war on the movement of population. The influence which the direct losses, that is, the deaths as a result of wounds or sickness, have exercised in recent times on the number of the population is relatively small. Even in the war of 1870-1871 the losses amounted to only 1 per cent. of the entire population of Germany. As opposed to the direct losses, the indirect loss of population is essentially larger, since wars exercise an especial influence on those factors which are fundamental for the further development of a people, particularly on marriages and births on the one hand, and on the general mortality on the other. Every great war reduces at first the number of marriages to a considerable degree. The diminution in the years of war, however, is followed in later years by so much more marked increase of marriages that the loss is again compensated. Still greater is the diminution of births as a result of the war which cannot be fully explained by the diminution of marriages and the absence of many men, but is also to be referred to psychologic hindrances among those who remain behind. Here also there follows in the years after the war a considerable increase, so that the loss is quickly replaced. Finally, the entire mortality, in many wars, is markedly increased by the fact that on account of them, great epidemics occur in the civil population and demand many victims. In many wars of previous centuries, these losses through epidemics have actually been much greater than the essential losses from the war, and have led to the complete depopulation of many cities. A peculiar phenomenon is the increase of emigration which almost always makes itself evident after great wars, and may have its basis in the political and economic and personal changes which every war involves. What influence the present war will exercise on the population and on the movement of population of the German Empire cannot yet be predicted. It may be assumed with certainty that the unfortunately marked reduction in the birth rate, which began in Germany about ten years ago and could not be arrested by any of the numerous measures directed against it, will be checked so that after the war another marked increase of births will set in. If that is the case, the war, in spite of the great sacrifice of human life, will be a blessing for the development of our entire population.

Association News

THE SAN FRANCISCO SESSION

Exposition Memorial Auditorium Will Accommodate All the Meetings with the Exception of the General Meeting

The annual session to be held in San Francisco next June will be unique in that all the meetings—the House of Delegates, the entire Scientific Assembly (except its first meeting, the General Meeting), the Registration Bureau, the Scientific Exhibit and the Commercial Exhibit—will be held under one roof. The Exposition Memorial Auditorium has been placed at the disposal of the Association for the week of the session, and provides ample accommodations for all the section meetings. The Memorial Auditorium occupies an entire block and forms part of the civic center. It, the city hall and other municipal public buildings are grouped and form an impressive area. The Auditorium itself is bounded by Grove, Larkin, Hayes and Polk streets. The group of buildings comprising the civic center is at a central point and is easily accessible from all sections of the city. Market Street, a wide thoroughfare leading to the ferry and steamship terminals on the water front, is directly adjacent. From the western boundary of this civic center, the Van Ness Avenue Municipal Street Railway leads directly to the exposition. The trip from the Auditorium to the exposition ground will take less than fifteen minutes.



The Exposition Memorial Auditorium. All the meetings—the House of Delegates, the entire Scientific Assembly (except the General Meeting), the Registration Bureau, the Scientific Exhibit and the Commercial Exhibit—will be held in this building.

The Memorial Auditorium, the building and equipment of which cost in round numbers $1,250,000, will be given to the city of San Francisco at the close of the exposition as a permanent memorial. This building has eleven halls, each with a seating capacity of from 400 to 10,000 people. In addition, there are nineteen rooms which will accommodate from thirty to 125 people. Rolling partitions on the third and fourth floors permit dividing some of the larger halls so that it is possible to provide fourteen halls, each with a minimum capacity of 250. By the use of these rolling partitions the Auditorium can at the same time provide for twenty-one meetings with an attendance of from 250 to 10,000, and will have still in reserve nineteen committee rooms which can accommodate from thirty to 125 people. The building is four stories high, with a large auditorium extending throughout its entire height in the central portion. Around this auditorium are wide corridors on all sides except at the rear where the entrance is directly from the street. Around three sides of the Auditorium there is a large balcony. Ample exits from the balcony to the corridors are provided at the different floor levels, and wide stairways extend from these corridors to the main floor. In addition, elevators connect the different floors of the building. A skylight at the top of the pyramidal roof furnishes light to the interior, and in addition, electric lights on the ceiling and walls give whatever necessary artificial light may be desired.

The main hall of this auditorium will be devoted to the Registration Bureau, together with the postoffice and information desks, and the commercial exhibits.

The wide corridor or foyer along the front of the building on the first floor will house a popular public health exhibit, part of the general plan for commemorating the service medical science has rendered. The corridor on the second floor, immediately above, will be used for the more technical portion of the scientific exhibit. On either side of this auditorium, and separated from it by wide corridors, are wide convention halls. These halls on the different floors of the Auditorium will be assigned to the scientific sections so that, as has already been stated, all the section meetings during this annual session will occur under one roof. The nearest approach to this convenient arrangement which the Association has been able to provide was in 1913, when the halls of the University of Minnesota permitted holding all the sections on the campus of the university. Much satisfaction was expressed by the Fellows who attended the Minneapolis meeting because all the Sections were accommodated in comfortable and commodious halls situated one near to the other. In San Francisco, this plan is followed even more fully.

Attention is again called to the arrangements which have been completed, whereby comfortable and reasonably priced quarters may be assured those who go to San Francisco. The subcommittee on hotels of the Local Committee on Arrangements states that the Hotel Bureau will be able to locate those Fellows, who request it, in hotels adjacent to the Civic Center in which the Exposition Memorial Building is situated. This Bureau, as previously announced (The Journal, February 20, p. 680, and February 27, p. 758), is operated in connection with the Panama-Pacific International Exposition and the San Francisco Hotel Association. A deposit of $5 will guarantee rooms to all those who make their reservations in advance. There is every promise of great convenience and pleasant arrangements for the annual session at San Francisco.

The Truth.—Perhaps there is one function of the scholar which should be cherished above all others. It is to discover and tell the truth. In spite of our many and increasing agencies for disseminating information, it seems just as difficult as ever to get at the truth about any given subject. It is not always palatable and has occasioned great disturbances. Many scholars have been compelled to fight and suffer for what they firmly believed to be the truth. Even to-day the scholar's truth is not always acceptable.—Theobald Smith, *Boston Med. and Surg. Jour.*

Marriages

Clarence William Anderson, M.D., Duluth, Minn., to Miss Lovena Rasmussen of Mabel, Minn., at Minneapolis, February 10.

Grover C. Bullington, M.D., Nokomis, Ill., to Miss Margaret Christian of St. Louis, Mo., at Springfield, Ill., February 17.

Joseph E. G. Waddington, M.D., to Miss Antoinette Marie Margraf, both of Detroit, at Windsor, Ont., February 15.

Louis Robert Melnikoff, M.D., Chicago, to Miss Mae Arkin of Hammond, Ind., February 23.

Creswell T. Pigot, M.D., Roundup, Mont., to Miss Alice Lowry of Butte, Mont., February 10.

James H. Fonger, M.D., Gary, S. Dak., to Miss Lucille Eakins, recently.

Deaths

Homer Gibney, M.D. Atlanta (Ga.) Medical College, 1893; a member of the Medical Society of the State of New York and New York Academy of Medicine; professor of orthopedic surgery in, and secretary of the New York Clinical School of Medicine; assistant surgeon to the Hospital for Ruptured and Crippled, New York; consulting orthopedic surgeon to the Italian Hospital, Somerville, N. J., and to the Rockaway and Tarrytown hospitals; orthopedic surgeon and president of the medical board of the West Side German Dispensary, New York City; one of the best-known orthopedic surgeons of New York; died at his home in that city, February 16, aged 55.

Andrew Sabine, M.D. Jefferson Medical College, 1856; the oldest practitioner of Weston, Kan., surgeon of U. S. Volunteers during the Civil War; mayor of Garden City, Kan.; at one time a member of the State Board of Health; for several years a member of the board of education and for more than twenty years local surgeon for the Sante Fe system; died at his home in Garden City, February 14, aged 84.

James Calhoun Brobst, M.D. Bellevue Hospital Medical College, 1867; assistant surgeon of the Forty-Sixth Pennsylvania Volunteer Infantry during the Civil War; superintendent of the Lititz Springs (Pa.) Sanitarium; chief burgess of Lititz and president or director of many of the local commercial activities; also a druggist; died at his home in Lititz, Pa., February 15, from senile debility, aged 70.

Hugh Young Brady, M.D. Western Pennsylvania Medical College, Pittsburgh, 1889 (license, Fayette County, Pa., years of practice, 1881); a veteran of the Civil War; for forty-five years a practitioner of Ohiopyle, Pa., and a member of the school board and common council; died at his home in that place, February 14, from cerebral hemorrhage, aged 74.

Omar Alpha Flint, M.D. University of Vermont, Burlington, 1885; formerly superintendent of schools of Billerica, Mass.; a member of the Massachusetts Medical Society; at one time superintendent of the Westboro Reformatory and a member of the staff of the Tewkesbury State Hospital; died at his home in Dracut, Mass., February 16, aged 71.

Francis Hustace, M.D. College of Physicians and Surgeons in the City of New York, 1874; a member of the Medical Society of the State of New York, while suffering from an attack of vertigo, February 17, fell from a window in his apartment on the twelfth floor of the Heimscott Building, New York City, and was instantly killed, aged 64.

Edward G. Husler, M.D. Jefferson Medical College, 1881; of Carnegie, Pa.; vice-president of the Carnegie Trust Co., Pittsburgh; a director of the First National Bank of Carnegie and one of the largest real estate owners in the Chartiers Valley; died in the West End Hospital, Pittsburgh, February 14, from heart disease, aged 61.

John Saxton Deemy, M.D. Medico-Chirurgical College of Philadelphia, 1890; a Fellow of the American Medical Association; one of the organizers of the Logan County (Ohio) Medical Society and local surgeon of the Big Four system at Bellefontaine, Ohio, died at his home in that place, February 13, from pneumonia, aged 48.

Judson Giles Kilbourn, M.D. New York University, New York City, 1884; a Fellow of the American Medical Association and a well-known surgeon of central New York; consulting surgeon to St. Elizabeth's Hospital, Utica, and surgeon to St. Luke's Hospital, Utica; died at his home in that city, February 16, aged 55.

James Joseph Scannell, M.D. Tufts College, Boston, 1905; of Brighton, Boston; director of the bacteriologic laboratory of the Boston Board of Health; formerly visiting physician to St. Mary's Infant Asylum; died in Carney Hospital, Boston, February 19, from pneumonia following an operation for gastric ulcer, aged 39.

Louis J. P. Des Rosiers, M.D. University of Victoria College, Coburg, Ont., 1872; medical health officer of Montreal in 1884; a member of the city council of Montreal for several years; died at his home in that city, February 12, from internal injuries sustained in a fall three weeks before, aged 78.

Albert Samuel Cooke, M.D. College of Physicians and Surgeons in the City of New York, 1901; of Brooklyn, who had had seven years of hospital work in Germany and who went to Valemova, Servia, in November, 1914, in the service of the Servian Red Cross; died recently in Servia, aged 36.

James K. Donoghue, M.D. Georgetown University, Washington, D. C., 1909; for two years a member of the staff of the Central Islip State Hospital, Long Island, N. Y., but for the last year a practitioner of Rochester, N. Y., died at his home in that city, February 14, from pneumonia, aged 28.

Francis Elias Whitlock, M.D. Jefferson Medical College, 1914; a member of the house staff of St. Alexis Hospital, Cleveland; for several years superintendent of the water works at Fostoria, Ohio; died at the home of his parents in Urbana, Ohio, February 8, from tuberculosis, aged 32.

James Ashley Bangs, M.D. University of Vermont, Burlington, 1884; of Iron Mountain, Mich., and physician for the Pewabic Company; for four years a resident of Denver; died at his home in that city, January 28, from tuberculosis, aged 59.

Russell Henry Wheeler, M.D. Northwestern University Medical School, Chicago, 1898; for many years a practitioner of Rapid City, S. Dak.; died at a hospital in Leavenworth, Kan., February 11, from cerebral hemorrhage, aged 43.

Adam B. Simmons, M.D. Eclectic Medical Institute, Cincinnati, 1867; a veteran of the Civil War and later a practitioner of Morrison, Ill., and California; died at his home in Chino, Cal., February 7, from influenza, aged 78.

J. Wallace Daniel, M.D. Atlanta (Ga.) Medical College, 1894; formerly a Fellow of the American Medical Association; a member of the Medical Association of Georgia; died at his home in Claxton, Ga., Dec. 16, 1914, aged 42.

Edward Harper, M.D. Pulte Medical College, Cincinnati, 1887; of New Orleans; secretary of the Louisiana Homeopathic Board of Medical Examiners; died in the Touro Infirmary, New Orleans, February 4, aged 51.

Charles Joseph Stark, Jr., M.D. Long Island College Hospital, Brooklyn, N. Y., 1912; of Woodhaven, L. I., N. Y.; also a druggist; died suddenly in Brooklyn, N. Y., February 11, from heart disease, aged 33.

S. B. Lee (license, Georgia Eclectic Board, 1901), professor of hydro- and mechanical therapeutics in the Hospital Medical College, Eclectic, Atlanta, Ga.; died at his home in Red Oak, Ga., February 7, aged 56.

James Ford Simpson, M.D. University of Nashville, Tenn., 1904; of Athens, La.; died in the Schumpert Memorial Hospital, Shreveport, La., February 11, a day after an operation for appendicitis, aged 38.

Lawrence Mitchell Cremin, M.D. New York University, New York City, 1881; of New York City; a member of the Connecticut State Medical Society; died in Bridgeport, Mass., Dec. 16, 1914, aged 54.

Samuel S. Eidler, M.D. Rush Medical College, 1865; of Wichita, Kan.; for many years a practitioner of Streator and Ottawa, Ill.; died in San Antonio, Tex., January 24, from cerebral hemorrhage, aged 79.

Edward Francis Ford, M.D. Maryland Medical College, Baltimore, 1891; a physician and druggist of Chester, Pa.; died in the Chester Hospital, February 4, from cerebral hemorrhage, aged 39.

John D. Skilling, M.D. Western Reserve University, Cleveland, Ohio, 1865; surgeon of U. S. Volunteers throughout the Civil War; died at his home in Lonaconing, Md., February 8, aged 87.

A. S. Kirk (license, Mississippi), a practitioner of Winston County, Miss., for more than fifty years; died at his home in Louisville, Miss., February 9, aged 76.

John Henry Boothe, M.D. Medico-Chirurgical College of Philadelphia, 1899; a member of the Medical Society of the State of Pennsylvania; died at his home in Philadelphia, January 3, aged 46.

Francis A. Tappan, M.D. Kansas City (Mo.) Medical College, 1871; at one time assistant city physician of Kansas City; died at his home in Kansas City, Mo., February 1, aged 71.

Amos Hagar Peirce, M.D. Boston University, 1882; a Fellow of the American Medical Association; died at his home in West Newbury, February 9, from heart disease, aged 54.

Oscar Fred Thornton, M.D. St. Louis College of Physicians and Surgeons, 1909; of Vaughan, Ark.; died at the home of his father in Lick Creek, Ill., January 29, aged 29.

Albert Elbridge Singer, M.D. Miami Medical College, Cincinnati, 1880; formerly of Dayton, Ohio; died at his home in Lewisburg, Ohio, February 7, from nephritis, aged 66.

Charles Scott Meeks, M.D. Memphis Hospital Medical College, 1909; died at his home near Columbus, Miss., January 1, from an overdose of chloroform, aged 30.

Milton J. Bolan (license, Indiana, 1897), for nearly fifty years a practitioner of Indiana; died at his home in Peru, Ind., February 4, from senile debility, aged 85.

Charles L. Powers, M.D. Hahnemann Medical College, Chicago, 1878; a pioneer practitioner of Coffeyville, Kan.; died at his home, February 3, aged 70.

Sampson Eagon, M.D. University of Virginia, Charlottesville, 1857; died at his home in Dallas, Tex., January 30, from cerebral hemorrhage, aged 79.

Michael Jacob Beard, M.D. Miami Medical College, Cincinnati, 1891; died at his home in Lucasville, Ohio, February 5, from disease of the lungs, aged 46.

Daniel W. Finnimore, M.D. Fort Wayne (Ind.) College of Medicine, 1881; died at his home in Potsdam, N. Y., February 7, from nephritis, aged 60.

Paul Koeper, M.D. Rush Medical College, 1899; a Fellow of the American Medical Association; died at his home in Baxter, Ia., Dec. 11, 1914, aged 43.

Victor Weinstein, M.D. Bennett Medical College, Chicago, 1910; died at his home in Chicago, Dec. 21, 1914, from angina pectoris, aged about 60.

Jesse B. Pardew (license, Arkansas, 1903), for twenty years a practitioner of Argenta, Ark.; died at his home in that city, February 5, aged 62.

Charles Franklin Addis, M.D. Kentucky University, Louisville, 1906; died at his home in Rineyville, Ky., January 28, from tuberculosis, aged 36.

Truman Coates, M.D. University of Wooster, Cleveland, 1888; of Oxford, Pa.; died in the Polyclinic Hospital, Philadelphia, February 1, aged 62.

William Hasenbalg, M.D. Cooper Medical College, San Francisco, 1882; of Castro Valley, Alameda County, Cal.; died Nov. 27, 1914, aged 62.

Joseph Walter Sim, M.D. University of Maryland, Baltimore, 1892; health officer of Glenwood, Md.; died at his home, January 8, aged 57.

Lewis Stiles Rogers, M.D. Chicago Medical College, 1853; of San Pedro, Cal.; died at his old home in Bakersfield, Cal., Dec. 6, 1914, aged 79.

James H. Glass, M.D. College of Physicians and Surgeons, Baltimore, 1884; died at his home in Paso Robles, Cal., January 8, aged 57.

Henry C. Shipley, M.D. University of Maryland, Baltimore, 1865; of Washington, D. C.; died in Sykesville, Md., February 11.

James Ford Hodge, M.D. Tulane University, New Orleans, 1886; died at his home near Walnut Lane, La., January 30.

John William Chambers, M.D. University of Michigan, Ann Arbor, 1874; died at his home in Oketo, Kan., February 4, aged 64.

Nelson Lucius Dow, M.D. Hahnemann Medical College, Chicago, 1887; died at his home in Glover, Vt., Dec. 1, 1914, aged 53.

Anal A. Carruth, M.D. New Orleans School of Medicine, 1858; died at his home in Wilson, La., February 5, aged 77.

S. J. Oliver, M.D. Medical College of Georgia, Augusta, 1887; died recently at his home in Waynesboro, Ga.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

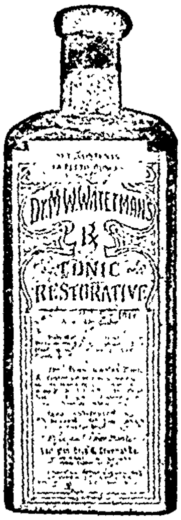
SOME MORE FRAUDULENT EPILEPSY CURES

The Waterman-Perkins-Kline Group of Nostrums

WATERMAN'S TONIC RESTORATIVE

The Waterman Institute of New York is one of the names under which Alexander W. Chappell has advertised "cures" for epilepsy and for the morphin habit. Chappell, who is said to be in the real estate business at Red Bank, N. J., also has operated under the name of the Lexington Drug and Chemical Company, which put out the Waterman "epilepsy cure." He is said to have been the principal owner of the "Aldine Laboratories" and the "Windsor Laboratories," and to have been formerly connected with a concern known as the "Berlin Remedy Company."

The advertising methods of the Waterman concern have been as vicious as its products. Whether advertising its morphin-loaded "dope" for unfortunate drug addicts or its bromid-loaded nostrum for epileptics, it has deluded and defrauded the public by means of advertisements prepared in the form of news items. For years certain newspapers published these advertisements in such form as to lead the unwary to believe they were telegraphic dispatches sent out to the newspapers. More recently, thanks to a government ruling on the subject, most of the newspapers carrying the Waterman advertisements have placed the tell-tale letters "*Adv.*" at the end of these items.



Apparently, it is not from New York alone that Chappell carries on his business. Newspaper advertisements identical in general appearance and wording with those of the Waterman Institute "news items" have been published telling of the marvelous results alleged to have been achieved in the treatment of epilepsy by one Dr. H. W. Perkins of Red Bank, N. J. Perkins apparently acts for Chappell both under his own name and also under the name of the Dr. R. H. Kline Company, a nostrum concern having the same address as the Lexington Drug and Chemical Company and, like it, said to be owned or controlled by A. W. Chappell.

Those who sent their money to the Waterman Institute for the "epilepsy cure" received a bottle of "Dr. M. W. Waterman's Tonic Restorative"; those who prefer to get the nostrum through Perkins of Red Bank receive "Prescription 909—Dr. Perkins' Favorite Prescription," while those who "fall for" the Dr. Kline fraud, get a bottle of "Dr. Kline's Nerve Remedy." The price is the same in any case—two dollars a bottle.

About a year ago there seemed to be an insurrection in the Waterman Institute camp. For years the letters sent out by the Waterman Institute, whether in connection with its villainous "morphin cure" or with the "epilepsy cure" have been signed "Lewis Riley, M.D." But in January, 1914, a letter from the M. W. Waterman Institute came signed William J. Brady, M.D., in which Brady begged to inform you that he had "superseded Dr. T. Lewis Riley" and would take personal charge of your case in the future. Moreover, he hoped to "give your case greater personal attention" than his predecessor, Dr. Riley, had done. Shortly after the Brady letter there came one from 112 East Nineteenth Street, New York City, signed Lewis Riley, M.D. This read, in part:

"Remember I have always been your physician, I alone treated all cases of epilepsy and nervous diseases, for the Waterman Institute, and no one has my record or tonic formulas. Should you take medicines apparently the same, it would not have the lasting effect."

Riley further urged his correspondents to address all communications and *make all remittances payable* to the "Pure Drug and Chemical Company" of that city. In another letter Riley wrote, among other things:

"I have been informed that a Dr. Brady is writing to my patients on a letter headed 'Waterman Institute' stating he has new and original methods, and sends them a sample of some kind of medicine. Dr. Brady has none of my formulas and any one who has taken any of my records from the Lexington Drug and Chemical Company has done so without my consent. Kindly do not consider me responsible for any deleterious effects that may arise from the use of any remedy that I have not prescribed. He also infers that I have quit treating epilepsy and nervous diseases and turned my practice over to him. This is not the case and at no time has he ever been employed in my offices as a consulting physician."

Our records fail to show that there is any licensed physician in New York named Lewis Riley. There is, however, a Thomas Lewis Riley, who was graduated in 1897 by the Bellevue Hospital Medical College, and was licensed in New York in 1900, and in New Jersey in 1914. William J. Brady, Riley's successor, is, according to our records, a graduate of New York University Medical College, 1892, and was licensed to practice in New York in 1894.

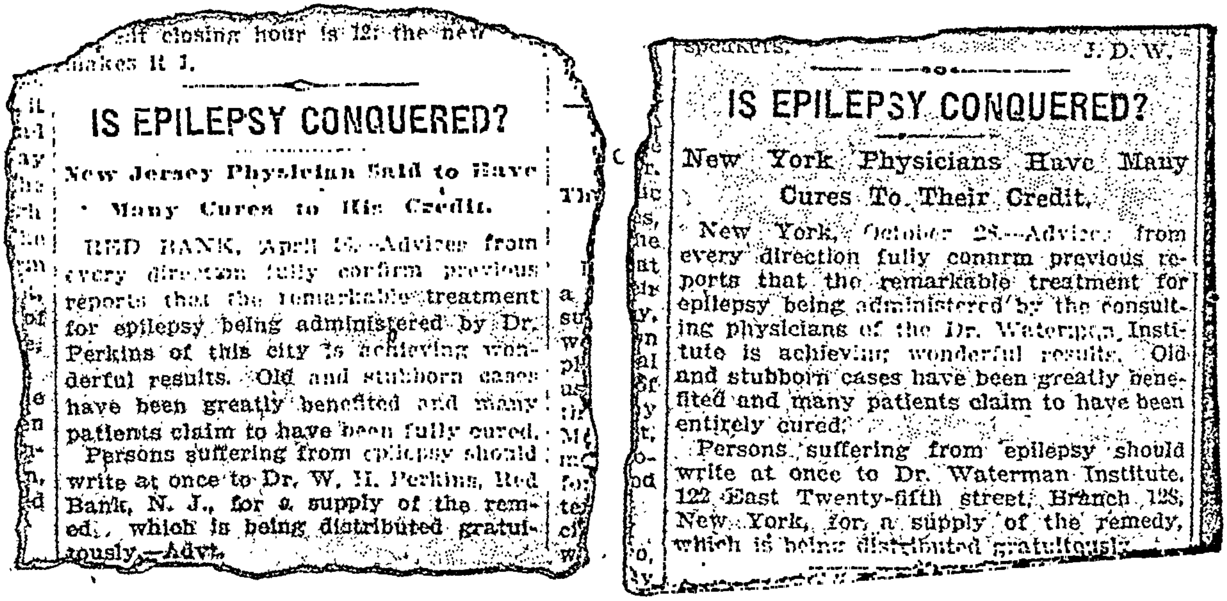
The "Dr. M. W. Waterman's Tonic Restorative" was analyzed in the Chemical Laboratory of the American Medical Association. The chemists' report follows:

CHEMISTS' REPORT[1]

One original bottle of "Dr. Waterman's Restorative," manufactured by Lexington Drug and Chemical Co., New York, N. Y., was submitted to the Chemical Laboratory for examination.

The bottle contained about 350 c.c. (11½ fluidounces) of a brown liquid, having extractive matter present and with an odor of cinnamon. The specific gravity at 15.6 C. was 1.1788. Qualitative tests demonstrated the presence of cinchona alkaloids, ammonium, potassium, sodium, chlorid and bromid. Quantitative determinations yielded the following:

Alkaloids (by weight)	0.04 per cent.
Ammonia (NH_3) (by weight)	1.30 per cent.
Potassium (K^+) (by weight)	2.70 per cent.
Sodium (Na^+) (by weight)	1.51 per cent.
Bromid (Br^-) (by weight)	16.36 per cent.
Chlorid (Cl^-) (by weight)	0.34 per cent.



...closing hour is 12; the new makes R. J.

IS EPILEPSY CONQUERED?

New Jersey Physician Said to Have Many Cures to His Credit.

RED BANK, April 15.—Advices from every direction fully confirm previous reports that the remarkable treatment for epilepsy being administered by Dr. Perkins of this city is achieving wonderful results. Old and stubborn cases have been greatly benefited and many patients claim to have been fully cured.

Persons suffering from epilepsy should write at once to Dr. W. H. Perkins, Red Bank, N. J., for a supply of the remedy, which is being distributed gratuitously.—Advt.

speakers. J. D. W.

IS EPILEPSY CONQUERED?

New York Physicians Have Many Cures To Their Credit.

New York, October 28.—Advices from every direction fully confirm previous reports that the remarkable treatment for epilepsy being administered by the consulting physicians of the Dr. Waterman Institute is achieving wonderful results. Old and stubborn cases have been greatly benefited and many patients claim to have been entirely cured.

Persons suffering from epilepsy should write at once to Dr. Waterman Institute, 122 East Twenty-fifth street, Branch 128, New York, for a supply of the remedy, which is being distributed gratuitously.

Dr. W. H. Perkins, of Red Bank, N. J., and the Dr. Waterman Institute of New York City are two names under which one A. W. Chappell seems to do, or to have done, business. The Kline Laboratories, New York City, is still another name used by the same man. All of the concerns sell "cures" for epilepsy. Perkins and the Waterman Institute have reached the public by means of advertisements prepared as news items. Two such advertisements are here reproduced. The letters "*Advt.*" following the items are a comparatively recent addition.

Essentially, each 100 c.c. of the solution contains approximately 8.8 gm. ammonium bromid, 9.7 gm. potassium bromid and 8.1 gm. sodium bromid. Calculating from the bromid determination, each meal-time dose, one teaspoonful (1 fluidram), contains the equivalent of 17.6 grains potassium bromid, and each daily dose (5 teaspoonfuls) corresponds to 88.0 grains of potassium bromid.

The directions on every bottle of "Dr. M. W. Waterman's Tonic Restorative" give the following dosage for adults:

"One teaspoonful after each meal and two at bedtime, in a wineglassful or more of water."

As the chemists' report shows, these five teaspoonfuls of the Waterman nostrum contain the equivalent of 88 grains of potassium bromid. As in all "epilepsy cures," the natural tendency of the person taking the Waterman nostrum is to increase the dose. This explains the testimonials that are written by those who use such preparations. By increasing the dose of the bromids to a point far beyond that of safety the epileptic attacks are suppressed at the expense of permanent injury to, and brutalization of, the patient. To the non-medical mind, suppression of the attacks passes for a "cure." That the Waterman concern, in common with other exploiters of "epilepsy cures," cares little for the health or safety of the person using its nostrum, is indicated by the statement appearing on the label under "Doses and Directions":

"Note.—If these doses are not sufficient to stop the 'Fits' and 'Spasms' increase the dose . . ."

In other words, the Waterman Institute would leave the dosage of the nostrum entirely to the judgment of the user. And the public is not told that the stuff contains bromids, while it is assured that the preparation is "safe." The fraudulence of "Waterman's Tonic Restorative" is evident.

Dr. Kline's Nerve Remedy

Dr. Kline's Epilepsy Cure used to be advertised under the name of Dr. R. H. Kline of Philadelphia. Now, it is sold by the Dr. R. H. Kline Company, 45-47 East Twentieth Street, New York—the same address as the Lexington Drug and Chemical Company, manufacturers of the Waterman "epilepsy cure." On both the letterhead of the Dr. R. H. Kline Company and the carton in which the preparation comes, it is stated that the concern has its "laboratories" at Red Bank, N. J. Red Bank, it will be remembered, is the home of A. W. Chappell and his employé, H. W. Perkins,

---

[1] This is a condensed report of the chemists' findings. The details of analysis will appear in the Reports of the Chemical Laboratory of the American Medical Association for 1915.

M.D., of "Dr. Perkins' Favorite Prescription." It is not surprising, then, that those who write to the Dr. R. H. Kline concern should receive a letter signed "H. W. Perkins, M.D."

Originally there seems to have been a Dr. R. H. Kline who for years quacked it in Philadelphia. In the advertising leaflets sent out by the Dr. R. H. Kline Company in 1914, no mention is made of the fact that Kline is dead, or, in fact, that he is not still in charge of the concern. In common with "Dr. M. W. Waterman's Tonic Restorative" and "Dr. Perkins' Favorite Prescription," "Dr. Kline's Nerve Remedy" also comes at two dollars a bottle.

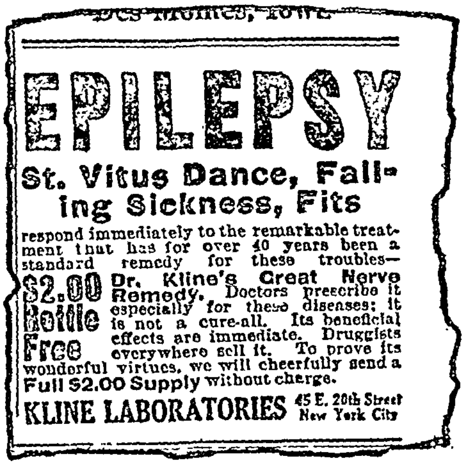
A bottle of Dr. Kline's Nerve Remedy was obtained and submitted to the Association's Laboratory for examination. The chemists' report follows:

CHEMISTS' REPORT[1]

One original bottle of "Dr. Kline's Nerve Remedy," manufactured by Dr. R. H. Kline Co., New York, N. Y., was submitted to the Chemical Laboratory for examination. The bottle contained about 350 c.c. (11½ fluidounces) of a brown liquid, having extractive matter present, and with an odor of cinnamon. The specific gravity of the liquid at 15.6 C. was 1.1740. Qualitative tests demonstrated the presence of cinchona alkaloids, ammonium, potassium, sodium, bromid and chlorid. Quantitative determinations yielded the following:

Alkaloids (by weight)	0.04 per cent.
Ammonia (NH_3) (by weight)	1.29 per cent.
Potassium (K^+) (by weight)	2.57 per cent.
Sodium (Na^+) (by weight)	1.50 per cent.
Bromid (Br^-) (by weight)	16.10 per cent.
Chlorid (Cl^-) (by weight)	0.23 per cent.

Essentially, each 100 c.c. of the solution contains approximately 8.7 gm. ammonium bromid, 9.2 gm. potassium bromid and 8.0 gm. sodium bromid. Calculating from the bromid determinations each meal-time dose, one teaspoonful (1 fluidram), contains the equivalent of 17.2 grains potassium bromid, and each daily dose (5 teaspoonfuls) corresponds to 87.0 grains potassium bromid.



EPILEPSY

St. Vitus Dance, Falling Sickness, Fits

respond immediately to the remarkable treatment that has for over 40 years been a standard remedy for these troubles—Dr. Kline's Great Nerve Remedy. Doctors prescribe it especially for these diseases; it is not a cure-all. Its beneficial effects are immediate. Druggists everywhere sell it. To prove its wonderful virtues, we will cheerfully send a Full $2.00 Supply without charge.

KLINE LABORATORIES 45 E. 20th Street New York City

A typical advertisement of the Kline Laboratories—a concern operated by the owner of the Waterman and Perkins frauds.

The report on Dr. Kline's Nerve Remedy shows that it is identical with the product put out under the name of Dr. Waterman's Tonic Restorative. The fractional differences that appear are not more than would be found in comparing any two analyses of the same product.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

THE HARRISON NARCOTIC LAW

To the Editor:—1. Is a physician dispensing his own remedies required to keep a record of cough mixtures, etc., containing only the minimum amount of opium, that is, 2 grains?

2. In dispensing to a patient when on a visit to him, if we leave 4 or 6 morphin ¼-grain tablets to be taken every one to four hours as directed, are we required to make and keep a record?

GEORGE D. CARNES, M.D., South Haven, Mich.

ANSWER.—1. No. The act does not apply to preparations which do not contain more than 2 grains of opium or more than one-fourth grain of morphin or more than one-eighth grain of heroin or more than 1 grain of codein, etc. Physicians dispensing remedies containing the minimum amount permitted of these drugs are not required to keep a record of them.

2. No. Drugs dispensed or distributed to patients by physicians in personal attendance on a patient need not be recorded (Article 10, Regulations).

To the Editor:—I ask you to notice the *Bulletin* of the Lycoming County Medical Society touching the new morphin-cocain act, which has been sent to you. What constitutional right has Congress to compel me to register before I may deal in and dispense these drugs? I am not engaged in interstate business. My business is confined to Pennsylvania. Pennsylvania has compelled me to comply with certain conditions before it gives me a permit to practice. It then compels me to register that permit and pay for it. It has the common decency, however, not to rob me of a fee each year for registering. Will you not look into this matter?

CHARLES J. CUMMINGS, M.D., Williamsport, Pa.

ANSWER.—Congress possesses the constitutional right to pass legislation regulating interstate commerce. The object sought in this case is the same as that sought in the passage of the law placing a prohibitive tax on the use of white phosphorus in the manufacture of matches, namely, the exercise of its legislative power for the public good. Both laws are in the guise of tax measures but are really for restrictive and not for revenue purposes. The tax of one dollar is not for revenue, but merely to make the law a revenue measure.

To the Editor:—I do not wish my name to appear in connection with this inquiry, but I believe answers in THE JOURNAL to the questions below will greatly help medical men:

Physicians must register and pay tax.

But: 1. Must a separate record and file of prescriptions be kept of those containing opiates and cocain? Will not the entry on our case records answer?

2. Must every such prescription have on it the name of the physician and his registered number and date of prescribing? If so, can all of these or any part be printed on the prescription blank? Will initials answer?

3. If a physician gives a hypodermic of morphin or sprays nose or throat with cocain must he make a record of it, and how complete must it be? Sprays and drops into eyes, etc., cannot be measured easily.

4. Must any record be made by a physician who orders a nurse to give a hypodermic of morphin?

5. Often a physician will direct a patient to refill for example a cough medicine if it distinctly aids him. Can this practice be continued?

N. S. D.

ANSWER.—1. Physicians are not required to keep a record of prescriptions. This cannot be emphasized too strongly. Physicians are only required to keep a record of narcotics dispensed. The prescription record is kept by the druggist.

2. Prescriptions for the drugs specified in the law must bear the signature in full of the physician, his registry number, the location of his office and the name and address of the person for whom such prescriptions are intended. There is nothing in the law or the regulations forbidding the registry number and the location of the office being printed on the blank. The physician's name must be "signed in full." Initials are not sufficient.

3. No. No record is required of drugs personally administered.

4. There is no distinct provision in the regulations on this point. A supplementary circular issued February 13 reads, "When visiting a patient in a hospital, a physician would

---

[1] This is a condensed report of the chemists' findings. The details of analysis will appear in the Reports of the Chemical Laboratory of the American Medical Association for 1915.

be considered as making a personal visit. . . . A visiting physician attending a patient in a hospital should be required by the hospital authorities when prescribing any drug falling under the scope of this law to place his initials on the chart or medicine sheet immediately after the drug prescribed." This requirement does not apply to state, county or municipal hospitals.

5. No. Prescriptions containing the specified drugs cannot be refilled. Regulations, Section 12 says, "If the physician desires the patient to continue taking a preparation, a new prescription must be written each time."

DIRECTIONS FOR MAKING DECINORMAL SOLUTION

To the Editor:—I should like to know how to make up a decinormal sodium hydroxid test solution.

E. J. G. Shults, M.D., Vienna, S. Dak.

Answer.—Decinormal alkaline solutions are usually made by diluting one part of the normal solution up to ten parts. Thus 100 c.c. of normal sodium hydroxid are put in a liter flask and diluted up to the mark with distilled water. The new solution is tested against a decinormal acid, which it should neutralize exactly, volume for volume. Directions for making normal sodium hydroxid solution are given in the United States Pharmacopeia.

THE USE OF THE LUETIN TEST

To the Editor:—The following phenomenon was noted by me recently, and as I have read or heard of nothing of the sort, I should like to report it.

A case of undoubted syphilis in the secondary stage with marked glandular and skin manifestations received prompt treatment with neosalvarsan, five maximal doses, and mercury, two courses of inunctions a year apart. After five months' rest from treatment, the blood Wassermann and provocative blood Wassermann tests were negative. After another rest period of several weeks, a luetin test was made and was doubtful, a tiny hard swelling being present from the first, not tender, with no areola, and perhaps 2 or 3 mm. in diameter. As the test was not absolutely negative, a short course of inunctions was decided on and begun in about ten days. On the fourth day, after two inunctions of mercury in the form of dilute ointment, of 2 gm. each, a very pronounced and typical luetin reaction was noted with considerable swelling, redness, tenderness and induration. This persisted for nearly ten days, slowly faded out and finally desquamated. The point of interest to me is this: Could this reaction be called a provocative luetin reaction and, if so, is it of any value? Has it any diagnostic or prognostic value? Perhaps it is simply a delayed reaction.

Charles E. Farr, M.D., New York.

Answer.—The luetin reaction is comparatively seldom positive in the secondary stage of syphilis. In such cases it may become positive when the treatment is instituted. The reaction in these cases, in which the Wassermann is likely to be negative, is of diagnostic value because it shows that the case under treatment is reacting to the treatment with the production of allergy. When such a positive reaction becomes negative again, it may be assumed that a temporary immunity has been established.

HIGH BLOOD PRESSURE AND THE HIGH-FREQUENCY CURRENT

To the Editor:—Can high blood pressure be permanently reduced by treatment with high-frequency current? If so, what is the technic?

John H. Murphy, M.D., Geneseo, Ill.

Answer.—There is no reliable evidence that high blood pressure can be permanently reduced by the high-frequency current. Temporary reduction of a few centimeters is secured by currents of a strength of from 400 to 500 milliamperes. This reduction is due to the heating effects of the current and the consequent dilatation of the peripheral blood vessels. If permanent results are to be secured, the treatment must include the ordinary dietetic and hygienic measures.

HYDRAMNIOS IN TWIN PREGNANCY

To the Editor:—Is acute hydramnios of one twin in twin pregnancy a rare condition? I have seen no mention of such a condition in any of the literature I have at hand.

T. F. Laurie, M.D., Auburn, N. Y.

Answer.—Hydramnios is especially frequent in unioval twin pregnancies. In such cases it is commonly the case that one twin exhibits the hydramnios and the other shows the reverse condition of oligohydramnios.

Wyoming: Laramie, March 11-12. Sec., Dr. H. E. McCollum, Laramie.

Arkansas Homeopathic November Report

Dr. Scott C. Runnels, secretary of the Homeopathic State Medical Board of Arkansas, reports the written examination held at Little Rock, Nov. 12, 1914. The total number of subjects examined in was 12; total number of questions asked, 120; percentage required to pass, 75. The total number of candidates examined was 3, all of whom passed. Two candidates were licensed through reciprocity. The following colleges were represented:

PASSED College	Year Grad.	Per Cent.
Arkansas Industrial University	(1889)	87
Boston University	(1890) 98.8; (1897)	94.4

LICENSED THROUGH RECIPROCITY College	Year Grad.	Reciprocity with
Denver Homeopathic College	(1902)	Oklahoma
Cleveland Homeopathic Medical College	(1907)	Oklahoma

Ohio Reciprocity Report

Dr. George H. Matson, secretary of the Ohio State Medical Board, reports that 10 candidates were licensed through reciprocity, Jan. 5, 1915. The following colleges were represented:

LICENSED THROUGH RECIPROCITY College	Year Grad.	Reciprocity with
Baltimore Medical College	(1909)	Maryland
Detroit College of Medicine	(1894)	Michigan
Univ. of Michigan, Dept. of Med. and Surg. (1899)	(1914)	Michigan
Dartmouth Medical School	(1908)	Maine
Bellevue Hospital Medical College	(1888)	Kentucky
Columbia University College of Physicians and Surg.	(1912)	New York
Cornell University	(1913)	New York
University of Pennsylvania	(1906)	Penna.
University of Pittsburgh	(1912)	Penna.

Rhode Island January Report

Dr. Gardner H. Swarts, secretary of the Rhode Island State Board of Health, reports the practical and written examination held at Providence, Jan. 7-8, 1915. The total number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 80. The total number of candidates examined was 4, all of whom passed. The following colleges were represented:

PASSED College	Year Grad.	Per Cent.
Yale Medical School	(1912)	89.9
Harvard University	(1908)	80
Tufts College Medical School	(1905)	80.4
University of Michigan, Dept. of Med. and Surg.	(1912)	92.7

Book Notices

Mechano-Therapeutics in General Practice. By G. de Swietochowski, M.D., M.R.C.S., Clinical Assistant, Electrical and Massage Department King's College Hospital. Cloth. Price, $1.50 net. Pp. 141, with 31 illustrations. New York: Paul B. Hoeber, 1914.

In his preface, the author recognizes the indifference on the part of medical men with regard to this important adjuvant in therapy, which he attributes to ignorance and to the neglect of the subject in the curriculum of medical schools. He says that the skill of the average man is quite sufficient to start with if shyness could only be overcome. Those who play on the piano or violin will find it a useful talent in this respect, too. Those who cannot rely on their fingers should leave massage alone altogether, rather than have recourse to vibrators, pulsators and other similar instruments. In experienced and reliable hands, however, these mechanical aids may be of service. The indications and contra-indications for the use of mechanotherapy are concisely stated. The technic is then described, with reference to fractures, sprains, dislocations, etc., and also with reference to chronic inflammations and various deformities. The second part of the book deals with the medical uses of massage. In this section it would seem as if more elaboration might be desirable. The treatment of the digestive system is included in seven pages, five of these being devoted to the treatment of constipation. While this brevity is disappointing in a certain way, it has the advantage that the book is restricted to a convenient size, and acquaintance with its contents or that of a similar guide should be regarded as an essential in the equipment of every physician.

Arbeiten aus dem Pharmazeutischen Institut der Universität Berlin. Herausgegeben von Prof. Dr. H. Thoms, Geh. Regierungsrat, Direktor des Pharmazeutischen Institutes der Universität Berlin. Eleventh volume. Paper. Price, 7 marks. Pp. 250. Berlin: Urban & Schwarzenberg, 1914.

This book represents essentially the eleventh annual report of work done in the Pharmaceutic Institute of the University of Berlin, and includes the publications of the year 1913. It includes reports from the division for the examination of medicaments, specialties and nostrums; reports of original work done in the division of organic chemistry, and reports on the work of the division for the examination of foods and other articles of consumption, and of technical products from the colonies. From a medical point of view, the comprehensive review of the new remedies introduced during the year 1913 is perhaps the more interesting in that it presents the essential information in a way that is readily understood. An article on the need for adequately controlling tinctures is also of importance, and serves to emphasize the nature of the control of pharmaceutic preparations that should be exercised by pharmacists. Altogether, this volume reflects the high class work done in the Pharmaceutic Institute of the University of Berlin, and might well be an incentive for the more progressive schools of pharmacy in this country to follow.

Mental Medicine and Nursing for Use in Training-Schools for Nurses and in Medical Classes and a Ready Reference for the General Practitioner. By Robert Howland Chase, A.M., M.D., Physician-in-Chief, Friends Asylum for the Insane. Cloth. Price, $1.50. Pp. 244, with 78 illustrations. Philadelphia. J. B. Lippincott Company, 1914.

This is a good manual for nurses. Nearly one-fifth of its contents is devoted to elementary physiology and psychology—a commendable feature of the book, the student being thus enabled to follow the author intelligently. The treatment is discussed in different chapters both from the physician's and the nursing points of view. On the whole, the subject is handled satisfactorily from the nursing aspect, but the physician who expects much information will be disappointed. The many illustrations have been borrowed from standard text-books on psychiatry and appear in poor print, whereas fewer but original drawings might have contributed much to improve the typographic appearance of the book.

Medicolegal

What Accounted Loss of Half of Finger

(In re Petrie (N. Y.), 151 N. Y. Supp. 207)

The Supreme Court of New York, Appellate Division, Third Department, affirms an award in favor of Petrie by the workmen's compensation commission, which allowed him for the loss of one-half of the third finger when it had been so injured as to require an amputation in which about one-third of the bone of the distal phalange was cut off. The court says that to call this error was taking a limited view of the statute, and one not justified by its remedial character. To get the true spirit of the act, it is only necessary to read the "phalange" clause in full, where, after providing that the loss of the first phalange shall "be considered to be equal to the loss of one-half of such thumb or finger," it continues: "The loss of more than one phalange shall be considered as the loss of the entire thumb or finger," etc. That is, the loss of any part of the second phalange, however slight or immaterial, should be construed as a loss of the entire finger, and yet the court was asked to hold that in the case of the first phalange the destruction must be entire to warrant a holding that this constituted a loss of one-half of the finger. Obviously the taking of one-half of the second phalange of a finger would not result in the relative loss that the taking of the first half of the first phalange would. After the first phalange is gone, what remains of the second, be it greater or less, is comparatively unimportant, yet the statute clearly and unmistakably provides that, where the loss involves "more than one phalange," the loss of the whole finger shall be held to have resulted. This, it seems to the court, is a legislative construction on the clause here under consideration. The substantial injury of the first phalange, requiring amputation, is to be understood as involving the loss of one-half of the finger, and, if the injury extends beyond the first phalange, then it is to be construed as involving the entire finger. Of course, a mere pinching of the finger, which does not result in a permanent injury, is not to be considered as the loss of half a finger.

Improper Use of Scientific Books in Cross-Examination

(Ullrich vs. Chicago City Railway Co. (Ill.), 106 N. E. R. 828)

The Supreme Court of Illinois reverses for error in the use of medical works in the cross-examination of expert witnesses a judgment rendered in favor of the plaintiff for personal injuries. The court says that the plaintiff claimed that before she was injured her health was good, but that after her injury in a street car accident she suffered from hysteria and peritonitis, and that those afflictions were the result of the accident. The defendant sought to show that hysteria can never be the result of or caused by accident, but is congenital. In the cross-examination of the plaintiff's expert witnesses, counsel for the defendant asked each witness whether he knew of or had read certain medical books, etc. During this time counsel exhibited, in the presence of the jury, various text-books, stating, at times, the one he was reading from during the cross-examination, and at one time stating that he had all the books on the subject. He did not offer in evidence any of the medical works which he pretended to have before him and which he used in the cross-examination of the witnesses, but he could not be permitted to do indirectly that which he was not allowed to do directly. He succeeded in conveying the impression to the jury that the witnesses were testifying against recognized authority on the subject of hysteria, which was the only purpose the court can perceive that he could have had in the use he made of the books. The cross-examination was improper and constituted reversible error. The law is well settled in Illinois that scientific books may not be admitted in evidence before a jury, and that such books cannot be read from to contradict an expert witness, except where such expert assumes to base his opinion on the work of a particular author, in which case that work may be read in evidence to contradict him.

CONFERENCE ON MEDICAL EDUCATION *

Held in Chicago, Feb. 16, 1915

The Eleventh Annual Conference of the Council on Medical Education of the American Medical Association, which was the largest in point of attendance in the history of the Council, met at the Congress Hotel, and was opened with an address by the chairman, Dr. **Arthur Dean Bevan**, Chicago, who said in part: We have recently made a revision of our third classification of medical colleges. During the last eight years the Council has made three separate classifications of medical schools, which have been regarded as temporary. In the last classification the schools were divided into four groups: A plus, A, B and C. The A plus group included those schools which, in addition to having a well-developed medical course, required a premedical science training for admission. Out of about ninety-eight medical schools that remain, however, eighty-four are now exacting this higher preliminary standard, and this has automatically eliminated the A plus classification. There is, therefore, no longer any reason for that special class.

The revised classification divides the schools of the country into three groups: An acceptable group, which the Council believes is worthy of full recognition by the state boards of the country; the C group, consisting of a limited number of schools which, in the opinion of the Council, are unworthy of recognition by state boards, and the B group, which includes schools in the doubtful class, the status of which should be determined by the state boards themselves.

The present classification places sixty-eight schools in Class A, the group of acceptable colleges including the Marquette University, School of Medicine, of Milwaukee, which has just been granted that rating. The New York Homeopathic Medical College and Flower Hospital, which was in the A group, has eliminated itself from that group by its failure to require for admission the premedical sciences of collegiate grade. That is automatic, as by instruction from the House of Delegates of the American Medical Association, no school shall be retained in the A group which does not require this premedical collegiate preparation. In the same manner a few schools will be automatically dropped into Class C unless they are so reorganized as to eliminate the stock feature, since under the instruction of the House of Delegates last June, no college is to be rated higher than Class C which is conducted as a stock corporation in the interest of the stockholders.

Eleven Years' Progress in Medical Education

Dr. **N. P. Colwell**, Chicago: Thirty-seven medical colleges began this year the enforcement of the entrance requirement of a college year in physics, chemistry and biology, joining the forty-seven which had already gone to that or higher entrance requirements, making altogether eighty-four medical colleges out of the present 100 operating under the higher standard.

The supply of medical schools in 1904 was far above normal, but has been reduced to an even 100 medical colleges. It will probably be further reduced by at least three or four by the end of June.

The percentage of medical colleges requiring two years of collegiate work exceeded that of the colleges requiring one year until 1913, when 33.7 per cent. required two years and 49.5 per cent. required one year. That the requirement of two years of collegiate work will eventually be the minimum requirement for admission to medical colleges in this country, however, is conclusively indicated by two factors. One is that the thirty-nine medical schools have already gone on that standard and that medical schools are so generally becoming medical departments of universities, where the two-year requirement is more satisfactory; the other is that already seven state medical licensing boards require two years of college preliminary preparation as an essential qualification for the license to practice medicine in those states, and the boards of several other states are about to adopt a similar standard.

Of the 100 medical colleges still existing, eighty-four have put into effect the requirement for admission of one or more years of collegiate work in addition to a high school education. In forty-seven colleges the higher requirement became effective in 1913 or earlier, and from forty-one of these, reports have been received showing this year's enrolments of students, and all but four report either increased enrolments, or larger freshman classes. In thirty-seven colleges the higher requirement began in 1914—at the beginning of the present college session—and, with one exception, these colleges had decreased enrolments, as was expected.

VARIATION IN MEDICAL COLLEGE ENROLMENTS

Figures showing number of colleges having enrolments in the session of 1914-15 larger, equal or smaller, respectively, than in the session of 1913-14.

Total Registration This Year	Number of Medical Colleges Requiring for Admission					Total Colleges
	Two Years of Coll. Work Effective in		One Year of Coll. Work Effective in		High School Course	
	1913 or Previous	In 1914	1913 or Previous	In 1914		
Increased...	22	..	7	1	3	33
Equal......	3	..	1	..	..	4
Decreased...	4 (3)	3 (1)	4 (2)	28 (2)	5	44 (8)
Totals....	29	3	12	29	8	81

Figures in parenthesis show number of colleges which, although the total enrolment was diminished, had larger freshman classes than a year ago.

Reports were also received from eight medical colleges which continue to admit students having only a high school education. Unusually large enrolments were expected in these colleges owing to the higher standards enforced elsewhere. It was surprising, therefore, that only three had increased enrolments, and in these the increase was small.

In the eighty-one colleges from which reports for the present session have been obtained, there are 12,235 students as compared with 13,568 in the same colleges a year ago — a reduction of nearly 10 per cent.

In the thirty-seven medical schools which began the higher requirement in 1914, the percentage of decrease varied considerably, depending on the thoroughness with which the requirement was enforced.

The lack of proper enforcement of preliminary standards in most of these colleges is apparently due to the lack of proper methods or to a misconception of what the educational standards really call for, rather than to an intentional disregard of those standards.

The weakest points in the administration of entrance requirements during the past year have been found to be: (*a*) the continued desire on the part of some colleges to obtain students by the use of makeshift methods; (*b*) the wide variation in the value of certain certificates of examination which students may present; (*c*) the lack of effective methods of certification and evaluation of credentials, and (*d*) the lack, in many schools, of competent officials who have become expert in evaluating credentials.

---

* The complete report of this conference, including the discussions, will be published in the March 15 number of the American Medical Association Bulletin. A copy will be sent to any address on receipt of 5 cents.

A routine method of verification of every credential presented by the student, therefore, whether it be a diploma or a certificate of examination, should be rigidly adhered to. A simple but effective routine method is as follows: (*a*) obtain from the student, in writing, a complete educational history showing when and in what school or schools his preliminary preparation was obtained; (*b*) obtain evidence from the most reliable sources regarding the standing of the schools or colleges attended—whether they are worthy of being accredited or not, and (*c*) obtain direct from the principal of the secondary school attended a statement giving the various subjects studied; the school year in which each was taken; the text-book used; the number of weeks covered; the number of periods per week; the length of the periods in minutes; the final grades obtained, and also whether or not the student graduated. A similar statement should be obtained from the registrar of any college attended, showing the time the student spent in college, the courses completed and the grades obtained.

Heretofore, in the administration of entrance requirements, the deans of medical colleges had chiefly to do with high schools; but now that entrance requirements have been advanced so as to include one or more years of collegiate work there comes the question: What constitutes "collegiate" work? It is well known that some colleges so-called are teaching little else than secondary school courses. In order to specify more clearly the actual education desired, the Council's educational standards suggest that "college work" should not be considered as such unless it has been preceded by a completed course of study in a standard four-year secondary school or its full educational equivalent. Such discrimination will at once eliminate the short-cut, secondary school-colleges which endeavor to crowd the work of several years into three or four. Such procedure will also be a powerful factor in standardizing the colleges of liberal arts.

There are now six medical colleges which require that hereafter every student enrolled must complete a year's internship in an approved hospital before he will be granted his M.D. degree.

On the whole, the progress being made along all lines of medical education is simply amazing to those who are in position to follow it. Much of the progress is within the medical schools, in the improved laboratories, the securing of more and better teachers, the close relations with hospitals and the improved methods of clinical teaching — facts that do not come to the attention of the casual observer.

The chairman presented Dr. Victor C. Vaughan, chairman of the Committee on Reorganization of Clinical Teaching, who read a paper based on the reports received from the individual members of the committee (see page 785).

DISCUSSION

Dr. William H. Welch, Baltimore: The time has come, as is recognized by the Council, to approach the important problem of clinical teaching and the organization of medical clinics. It is unquestionably a fact that there has not been a corresponding advance on the clinical side comparable to that on the laboratory side.

As to the full time system minus the provision that the head of the clinic shall receive a salary which will enable him to be independent of seeking other sources of income from private practice, we have not attempted at the Johns Hopkins to go quite to the extent of the full time proposition which is advocated. There is a little too much emphasis put on the full time plan running down through the whole system below the head of the department. We were very careful in presenting the subject to the General Educational Board to indicate that there would be a very important need in the medical school of men engaged in practice, and some of the physicians suggested as full time men had better be part time men.

As to how the medical school is to obtain a teaching hospital, the university has to provide its own. The future will depend on properly endowed hospitals, but above all, public hospitals, municipal hospitals, supported by public funds, being placed, as they are in Europe, to a very large extent at the disposal of the medical schools for teaching purposes.

As to the hospital year, I think it is premature for us at the moment to require this year for a degree. If we are to have another year added, it is a serious matter from the point of view of medical education. It is not perfectly clear that that is the best use of the added year, and it is a year over which the university conferring the degree has very little control.

President Henry S. Pritchett, of the Carnegie Foundation for the Advancement of Teaching, New York: It seems to me, it is clear that the clinical teacher must have as his primary work the work of the school and hospital; that it is no longer possible to administer a very large practice and be at the same time a clinical teacher of the type which is now necessary. I think in many medical schools clinical teachers fail to realize how quickly raising the entrance requirements has reacted on the clinical teachers. Once you require a student to be fairly well educated, he is no longer going to be satisfied with the kind of clinical teaching which was perfectly acceptable ten or twenty years ago, and so we may assume as the outcome of this discussion that the medical profession and medical teachers are ready to accept the principle that the clinical teacher must be, first of all, a worker in the school and hospital and his practice must be secondary. In the second place, it is perfectly clear that if he is to give his primary work to the school and hospital, then the facilities for such work must be afforded. There is no use in having a man whose primary work is that of teaching and who is engaged in hospital work, unless the facilities are adequate for laboratory work.

Dr. George Dock, St. Louis: I think what Dr. Welch has said about the intern year is extremely well taken. I myself have taken the same ground ever since the movement for the intern year started. We need a clinical clerk year much more than an intern year, for the reason that very few hospitals are satisfactory training grounds now for well-trained medical students.

Dr. Samuel W. Lambert, New York: There is only one point I would like to emphasize, and that is entirely connected with the financial side in the reorganization of clinical instruction. It costs medical schools now about three times as much money per student as that student pays in tuition fees, even in schools that have between 300 and 400 students. The great problem for most schools to-day is to devise some scheme by which the two corporations — one the medical school and university, and the other the hospital — can work together for the common good of medical education.

Dr. J. M. Baldy, Philadelphia: No school can hope, unless it has an exceedingly small class, personally to control sufficient hospital facilities to give an ideal internship. If the internship is to be a success, the trustees of hospitals and of school hospitals must see that the proper facilities for such are afforded.

President George E. Vincent, of the University of Minnesota, then read a paper on "The University and Higher Degrees in Medicine" (see page 790).

DISCUSSION

President Harry Pratt Judson, of the University of Chicago: There are many physicians who would find it to their advantage to go back to a medical school and undertake work of various kinds in order to bring themselves up to the point of advanced medical science. They desire to refresh their knowledge of certain things which they did not take a strong hold of in their undergraduate days. They want to make themselves more efficient and more intelligent men. That is an excellent function of a graduate school connected with a medical school. In all graduate schools there are a small number of students or doctors of medicine who will be engaged in work of an advanced character that is entirely beyond the work carried on for the instruction of undergraduates, such as that involving especially productive investigation in some of the most recondite lines. It is the kind of work in which we wish to train a small number of choice men, and they are the ones who are doing the real graduate work about which President Vincent has spoken. That, it seems to me, will involve another very important consideration: For the class of work done by graduate students, the ordinary faculty giving undergraduate instruction in a medical school will suffice; but for the second class we must have choice men, men of power and breadth of vision engaged in large investigations, the kind of men essential for the guidance of a few choice students in medicine. If we are to develop in that line in our medical schools, it will become more and more essential for our universities to develop that kind of men and put them in charge of this kind of work. It cannot be class work, but it must be thorough, personal work, and it is a great privilege for any man of ambition to work with such men. It does not matter how long he works, provided he completes certain definite work.

Dr. William Charles White, Pittsburgh: On account of lack of thoroughness in the human individual, the great majority of all graduates of schools of medicine will be simply visualizers. I doubt whether it will ever be different. In the general hospitals in which medical education is given, as they are constructed to-day, we have excluded the great mass of diseases from which the populace suffers—tuberculosis, venereal diseases, infectious diseases — all the things that are demanded of the visualizers who are usually employed for this work. In addition we graduate technicians, certain mechanicians, surgeons and probably sanitary engineers, and I think it might be well in considering medical education to-day to hold back in a measure in the evolution and see if we cannot fulfil what will conduce to public welfare rather than to turn out a fully equipped, high grade technician as the result of our medical educational work.

Dr. M. J. Rosenau, Boston, then presented a paper on "Courses and Degrees in Public Health Work" (see page 794).

DISCUSSION

Mr. William C. Hoad, Professor of Sanitary Engineering, University of Michigan: As community life grows more complex, the civil engineer and the physician will be brought into more intimate relations. Both labor toward the same great end, and each will find himself able, through cooperation with the other, more and more effectively to serve his community and to discharge fully the high obligations laid on him by his profession. I am thoroughly convinced by the full and hearty cooperation of these two in public health work, that the present large administrative problems may be attacked from a surer base, the reputation of the health department will be enhanced, and new sources of support for it will be made available, and there will be opened up new fields of usefulness as yet unoccupied.

Preparation of Specialists in Ophthalmology and Otolaryngology

Dr. Frank C. Todd, Minneapolis: The University of Minnesota Medical School last year established courses for the preparation of specialists, not only in ophthalmology, but also in all branches of medicine, and in a modest way began the operation of that plan last September.

The requirements for admission to the courses in all departments are, first, graduation from a high grade medical school and, second, the completion after graduation of one year's internship in a general hospital or its equivalent. The courses then cover a period of two and three years, depending on the specialty and the length of time the student desires to devote to his work. On the successful completion of two years of work in any specialty, together with the completion and written report of a piece of research work, the student will be granted a degree, Master of Science, in whatever department he has conducted his work.

As to the time when it is best after graduation in medicine for the practitioner to begin his preparation for his specialty, I believe that whatever specialty he undertakes, the earlier, after securing his M.D. degree, the aspirant bends his steps in the direction of his specialty the better.

In ophthalmology and otolaryngology the student must acquire a detailed and thorough knowledge of anatomy of the head, face and neck, with especial reference to the eye and ear and air passages. During his three years' course it would seem to be necessary for a physician preparing himself to become a specialist in ophthalmology and otolaryngology to spend one-half of his time in laboratory and other work, not consisting of clinical work in ophthalmology and otolaryngology. This includes experimental surgery and some research work, for which time should be allowed and for which encouragement should be given. This leaves one-half the time for clinical work in ophthalmology and otolaryngology, which should commence at the beginning of his course. It will consist of history taking, of learning the technic of handling instruments, of daily work in assisting in the outpatient clinic and in assisting in operations, as well as following up the care of the patients at the bedside. Later, and after experimental work has been done on the cadaver and animals, and the student has demonstrated his fitness, he should be given opportunity to do the simpler operations at first and later the more complex ones.

DISCUSSION

Dr. Edward Jackson, Denver: With reference to a degree, speaking for myself and for my colleagues, if there is any general agreement on the subject to give the degree of Master of Science or Doctor of Science in ophthalmology or any other branch—and the proposition appeals to me strongly — if university authorities agree that this should be done. I am sure the University of Colorado will quickly fall in line with such a movement.

Report of the Committee to Investigate Graduate Medical Instruction

Dr. Horace D. Arnold, Boston, Chairman, presented the report on graduate medical instruction, which is abstracted as follows:

The problem of instructing graduates in medicine should be considered from the standpoint of the public good. The aim is to furnish better doctors to the public. Much has been accomplished by raising the standards of medical schools; and the problem of the proper training of medical students may be regarded as practically settled for the present. The most difficult and the most important problem to-day is that of raising the standard among physicians who are already in practice. It is clear that different classes of students need very different opportunities, and courses of instruction to meet their needs must vary from elementary to very advanced courses, students being admitted only to courses which they are qualified to take.

During the past year the committee inspected the more important "postgraduate" schools of the country—independent schools organized for the purpose of teaching medical graduates. These schools vary from good to very bad. Not only is the instruction poor and the equipment inadequate in many of them, but some are clearly commercial in type, carried on for the direct or indirect gain of the instructors. The existence of such schools, and the difficulty of controlling them, shows the weakness of the plan of depending on these independent schools for adequate instruction for graduates. Hence it is desirable that good medical schools should undertake this form of instruction as far as they are able.

The medical profession is becoming convinced of the necessity of establishing standards for specialists. Nothing brings greater discredit to the profession than the blunders of self-styled specialists who have had an inadequate training. The training of specialists is clearly a form of graduate instruction. It should involve a systematic course of instruction of at least one year, followed by a year or more of supervised clinical experience. This involves the organization of a graduate medical department, the possession of exceptionally good clinical facilities, and close affiliation with suitable hospitals. Such a course is worthy of recognition by some form of degree—a "higher" degree in medicine than M.D.—and it is desirable that such degrees should be granted only by universities. It is clear that only university medical schools which have exceptionally good opportunities should attempt the training of specialists.

Aside from opportunities for research, our best medical schools have made little provision for graduates who seek advanced instruction. Several of the schools, however, are beginning to give serious consideration to the problem of graduate teaching, and this should be encouraged. Instruction of this type should be of the highest grade, and the best schools may well consider that it is a duty they owe to the community to meet the demand for such courses.

The problem of graduate medical instruction is very different from that of the undergraduate school. There is no fixed curriculum, and no definite number of subjects that must be covered. It is creditable for a school to offer but a single course, if it is a good one, but discreditable to try to cover more ground than it can do well. If a school offers only a few courses, it is not necessary to have any special machinery or organization to take charge of the work. Each department can organize and manage such courses as it wishes to offer with a little extra work for the administrative force of the school. Only when this form of instruction is undertaken on an extensive scale is it desirable to establish a separate department or school.

Hitherto the better "postgraduate" schools have been successful because they had to compete only with poorer schools of the same class. If the good medical schools enter this field of teaching, these schools will have to come up to the standards of good medical schools or they will deteriorate and fall to the level of the poorer "postgraduate" schools, chiefly through the loss of their best teachers. Many of these men stand very high in the estimation of the profession. They are interested in graduate teaching more for the good it will do than for personal satisfaction and have become associated with "postgraduate" schools because there were no others where such teaching could be done. These men will not stay with schools of inferior grade if good medical schools undertake the work.

The best "postgraduate" schools have suffered in reputation by being placed in the same class with the poorer schools, and will suffer still more as attention is directed to standards. The solution of this difficulty would be to seek affiliation with good medical schools or with universities. To secure such affiliation, a "postgraduate" school must come up to the standard of the school with which it seeks affiliation. Few, if any, of these schools can hope for affiliation with the best medical schools on their present basis. They must bring their weak departments up to the standard before seeking affiliation; or they must be prepared, in arranging an affiliation, to drop poor instructors and to give up weak courses.

Owing to the great difference in the previous training of graduates who seek instruction, there can be no uniform admission requirements of an educational character. For the benefit of the public, even the most poorly trained practitioner, if he is legally entitled to practice medicine, should have an opportunity to improve his medical knowedge. It is also desirable, on the contrary, that graduates from poor schools who are not registered should not be able to coach up in these courses and learn just enough to pass the state licensing boards.

It is recommended that a certificate be regarded as a diploma; that the minimum time requirement be four months of all day work, taken consecutively; that it should be granted only for a systematic course, approved by the school, in which attendance and work have been satisfactory, and that the student must pass an examination based on this course of study. A school may issue for shorter courses an official statement as to a student's attendance or the character of his work; but the form must be such that it does not resemble a diploma.

The Council will not at present attempt to divide all the independent schools into those which are approved and those which are not approved. Any such school, however, may apply for the approval of the Council. Such approval may be granted if the school meets the requirements as to admission and certificates, and if, in all departments in which instruction is given it comes up to the standard of a Class A school.

DISCUSSION

Dr. James F. McKernon, New York: No distinct advantage is to be gained by putting restrictions or prohibitions in the way of any earnest practitioner. The more the student is restricted, the more you coerce him, the less will you guide him and the less you will teach him, and the less you benefit the community. I believe that the better class of postgraduate medical schools is doing a work that at the present time cannot be undertaken by any other institutions in this country. When the undergraduate schools give us better material, we will turn out a better finished product, but because the practitioners at large have deficiencies of early training we should not close the door of further medical instruction to them because of their lack of training.

Dr. George M. Kober, Washington, D. C.: The public is vitally interested in the solution of the question, If certain diseases are preventable, why are they not prevented? I hail with delight every effort that is being made by institutions of higher learning to afford facilities for the equipment of men to carry on this noble mission.

Dr. Walter L. Bierring, Des Moines, Iowa: It requires special facilities for graduate instruction in different lines for specialties, and it requires coordination of the engineering and medical courses to train health officers adequately, and it seems to me they have almost ideal arrangements for this combination at Harvard Medical School with the Massachusetts Institute of Technology which cannot be duplicated in many places in this country.

Dr. N. P. Colwell then presented a preliminary report on the "Standardization of Hospitals." Before the hospital internship could be made a fixed requirement for all medical college graduates, it was necessary to see whether there were enough good hospitals to provide the internships needed. Early in 1913 a preliminary investigation of the hospital situation was begun. This investigation showed that there were 924 hospitals in the United States having 100 beds or more, and 1,500 others having from twenty-five to 100 beds, or altogether 2,424 hospitals having over twenty-five beds. These hospitals had altogether 193,056 beds, or an average of ninety-two each, and would provide places for about 4,000 interns, allowing fifty beds per intern, or for 8,000 interns if there was one intern for every twenty-five beds. Since there were less than 4,000 medical graduates each year, if all these hospitals made use of interns, there would surely be enough places for all. But not all hospitals were using interns. Of the 2,424 hospitals, reports were received from 2,185, and of this number only 852 hospitals were regularly using interns, the total number of interns provided for being 3,006. Sufficient places, therefore, were not being provided, since in that year there were 3,981 medical graduates. One of the chief objects of a general investigation of hospitals, therefore, will be to induce a larger number of those which are approved to provide for the training of interns.

5 Threshold Stimulus of Chorda Tympani Nerve in Relation to Salivary Secretion and Vasodilatation. C. M. Gruber, Philadelphia.
6 *Factors Affecting Coagulation Time of Blood. VI. Effect of Rapid Progressive Hemorrhage on Factors of Coagulation. K. R. Drinker and C. K. Drinker, Boston.
7 Vasomotor Nerves of Portal Vein. R. Burton-Opitz, New York.
8 *Influence of Pupillary Diameter on Visual Acuity. P. W. Cobb, Cleveland.
9 *Effect of Repeated Injections of Pituitrin on Milk Secretion. S. Simpson and R. L. Hill, Ithaca, N. Y.

3. **Blood Transfusion in Pancreatic Diabetes.**—The transfusion of normal blood into dogs in pancreatic diabetes Carlson and Ginsburg found causes a temporary lowering of the hyperglycemia. But before this can be taken as an evidence of the presence in normal blood of an internal secretion from the pancreas, it must be shown that this temporary lowering of the hyperglycemia is due to storage and oxidation of sugar in the tissues. Their work indicates that sugar retained as a result of the blood transfusion is not subsequently excreted. If this is the case, what can happen to this sugar except oxidation in the tissues? In the first place, a temporary lowering of the rate of tissue metabolism might account for temporary fall in blood sugar. Or, the metabolism rate being the same, some of the sugar may disappear by way of the digestive secretions and bacterial oxidation in the digestive tract.

4. **Influence of Blood Transfusion on Kidneys.**—Rabens' results fail to bring any evidence of injury or depression of the kidneys by Carlson's method of transfusion.

6. **Effect of Hemorrhage on Coagulation of Blood.**—The Drinkers emphasize that rapid progressive hemorrhage causes a progressive decrease in coagulation time. An occasional animal proves an exception to this rule and shows no change in its rate of clotting, no matter how severe the hemorrhage. Antithrombin decreases in amount when the coagulation time decreases and remains practically constant when the coagulation time is unchanged. Prothrombin tends first to increase slightly in amount and then to decrease slightly. Fibrinogen, estimated by the heat coagulation method, decreases as hemorrhage progresses. Platelet counts do not vary with rapid progressive hemorrhage.

8. **Influence of Pupillary Diameter on Visual Acuity.**—By the use of circular diaphragms before the eye Cobb demonstrated that an aperture for optimal visual acuity exists somewhere between the limits 1 and 5.6 mm. for brightness of test-object from 5.9 and 189 candles per square meter. When the illumination of the test object is compensated for the size of aperture to give equally bright images on the retina, the optimum is somewhat less than when constant illumination is used and the brightness of the retinal image varies with the pupillary area. In the former case it falls at 2 to 4 mm., in the latter at 4 mm. on the average.

9. **Effect of Pituitrin on Milk Secretion.**—The administration of pituitary extract, by intravenous, intramuscular or subcutaneous injection to a lactating animal led to a marked increase in the quantity of milk secreted and also in its fat content. In the goat, if the injection was continued at intervals over a prolonged period—several months—immunity to its action on the mammary glands appeared to be established both in regard to the amount of milk yielded and the percentage of fat it contains.

13 Localized, Subacute Form of Bronchopneumonia. R. C. Larrabee, Boston.
14 Field for Local Anesthesia and of Spinal Anesthesia in Genito-Urinary Surgery. A. H. Crosbie, Boston.

10. **Treatment of Diabetes.**—Allen maintains that diabetes is not a disease but merely the weakness of a bodily function, namely, the function of assimilating certain foods. If diabetes is a weakness of the pancreatic function one can understand why the breakdown is most frequent in elderly persons, but generally most serious in young persons. Stop glycosuria by fasting, and then place the animal on a low diet which will support life without producing glycosuria. Such an animal is thin, but strong and lively, with no cachexia and no sign of downward tendency. The treatment for patients is similar. The first step is to fast till glycosuria ceases, and then for twenty-four or forty-eight hours longer. At the same time, the ketonuria falls steeply. It quickly approximates what a normal individual would show under similar conditions, and the aim is to keep it constantly down to this level. Plain fasting suffices for the purpose; but since alcohol is a food which does not produce glycosuria and is said to diminish ketonuria, it is generally given during fasting, especially if there is danger of coma. Its use or omission in later treatment depends on individual conditions. Alkalies may be useful for the first few days if coma seems imminent, but are then no longer needed.

When the fasting patient has been free from glycosuria for twenty-four to forty-eight hours, the next step is to begin feeding very slowly and cautiously. There need not be a fixed program. It is desirable to individualize the diet to suit the needs of different patients. The one requirement is that the patient must remain free from both glycosuria and acidosis. Any trace of sugar is the signal for a fast day, with or without alcohol. The original fast, to clear up the urine in the first place, may be anything from two to ten days, but after that no fast need be longer than one day. The things to be considered in the diet are carbohydrate, protein, fat and bulk. Frequently the first thing given after the fast is carbohydrate. No distinction is necessary between different forms of starch, but there are advantages in using vegetables. The first day after fasting, the only food may be 200 gm. of vegetables of the 5 and 6 per cent. classes. This is increased day by day until a trace of glycosuria appears, which is checked by a fast day. The purpose of such a program is to learn the carbohydrate tolerance and to clear up the last traces of acidosis. After this carbohydrate period, or sometimes in place of it, protein is given. On the first day perhaps one or two eggs are given, and nothing else. More protein, generally as eggs and meat, is added day by day, until the patient either shows glycosuria or reaches a safe protein ration. The purpose here is to learn the protein tolerance, and to cover protein loss as quickly as possible. Fat is somewhat less urgently needed, except in very weak and emaciated patients; it can be added gradually, as conditions seem to indicate. An element of bulk in the diet is necessary to give the comfortable feeling of fulness and to prevent constipation. This is the great advantage of green vegetables. When they are fed raw, or cooked in steam, or boiled and evaporated so that no water is thrown away, they contain a definite quantity of carbohydrate besides valuable salts; and this is the only form of carbohydrate that patients thus treated ordinarily receive. Some cases are so severe that even green vegetables cannot be tolerated. Under these conditions the vegetables may be boiled through three waters, throwing away all the water. Nearly all starch is thus removed, and the most severe cases generally take these thrice-cooked vegetables gladly and without glycosuria.

One result of the initial program described is the loss of weight. The attempt to put on weight, Allen says, is one of the surest ways of bringing back all the symptoms and sending the patient down hill. It is probably one of the chief causes of past failures in treating severe diabetes. In the severe cases it is found necessary to restrict all classes of food, and to test the tolerance of each patient for each particular class. Carbohydrate is given if possible, but is kept safely below the limit of tolerance. Protein must be kept fairly low, sometimes very low. With a dangerously low protein tolerance the working rule has been to exclude all carbohydrate, then feed as much protein as is possible without glycosuria. The histories of four of the twenty-seven patients so treated in the Rockefeller Hospital are cited.

45 Case of Convulsions in New-Born Baby. A. H. Beifeld, Ann Arbor.
46 Exfoliative Dermatitis and Granuloma Fungoides Showing Results of Treatment. U. J. Wile, Ann Arbor.

38. **Postoperative Ileus and Ileus Accompanying Peritonitis.**—The critical condition of a patient suffering with ileus, Andries says, is largely due to a loss of body fluids. Enterostomy, for postoperative ileus that will not quickly yield to stomach lavage and enemata is a life-saving measure. It is really Nature's method of effecting a cure. Enterostomy, in advanced cases of peritonitis in cases in which abdominal distention is marked, is a logical procedure and deserves universal adoption.

44. **Analysis of Mortality of Abdominal Surgery.**—It is Skeel's belief that proper selection of the anesthetic for the case and proper handling of the tissues together with correct determination of the amount of operating which the patient can safely stand will do more to lessen the mortality rate in the hands of the average surgeon than any attempt to follow spectacular methods under fanciful names which appear like a comet, loom large for a time and are forgotten so soon as the commotion produced by their unusual character has had time to subside.

75 Condensed Milk. P. Bartholow, New York.

61. **Pelvic Abscess Following Fowler Position in Appendicitis.**—Delatour emphasizes, that in those cases of septic peritonitis, in which the patient continues to show abnormal temperature, and the wound looks healthy, and careful examination of it shows no undrained pockets, be sure to make a rectal examination, especially if the patient is losing ground, and has frequent bowel movements, with tenesmus and the discharge of mucus. If on examination, an abscess is found, do not hesitate to drain it through the rectum. There is apparently little or no danger of infection from this source. To wait for the abscess to be reached easily from in front, is to lose valuable time, and the incision through the abdominal wall will leave a weak point for the development of hernia, as drainage must be continued for some time. While aspiration may prove satisfactory in some cases, we recommend incision whenever possible.

62. **Control of Hemorrhage in Suprapubic Prostatectomy.**—The method which has been entirely satisfactory in Fowler's hands is as follows: The tip of a tube of a suction apparatus with a direct inflow for hot solution is placed in the cavity from which the prostate has been removed. The inflow tube is connected with an irrigator containing boiling water. The sucking portion of the apparatus is connected with the vacuum bottle in which a vacuum is maintained in the usual manner by flowing water. The apparatus, before its introduction, is tested, for it is important that suction be perfect. Introduced into the cavity with the inflow tube shut off, all blood is sucked out, and while this suction is continued the boiling water is allowed to flow through the inflow tube into the cavity. The inflow is regulated so that the suction does not allow the boiling solution to come in contact with any but the raw tissues. After two minutes' application of the boiling solution hemostasis is complete, and the surrounding parts have not been injured.

64. **Preparation of Patients for Abdominal Operations.**—A single standard method used throughout all hospitals in preparing patients for abdominal operations is proposed by Graham. It is as follows: 1. Tasteless castor oil—1 ounce—on admission but not later than 7 p. m. 2. Tub bath, if necessary. 3. Shave, with tincture of green soap, followed by alcohol and allowed to dry while the mouth is inspected, dirty teeth cleansed with a cotton swab and, if necessary, painted with tincture of iodin. The razor should be sterile. 4. Paint the area with one-half strength tincture of iodin and apply sterile compresses. 5. Farinaceous diet is ordered and a pitcher of water and a glass placed by the bedside and the patient encouraged to drink freely. 6. Physical examination by the house surgeon. 7. Specimen of urine sent to

the laboratory for examination. 8. Enema at 9 p. m. and trional, grains 5, and sodium bromid, grains 30, given. 9. In the morning, weak tea or coffee or water allowed up to within two hours of operation, unless special contra-indication exists. 10. Emptying of the bladder or catheterization just before leaving for the operating room.

68. **Drainage of Seminal Vesicles.**—Operative drainage of the vesicles for chronic focal infection, Squier says, has produced in a series of 50 cases a cure in 68 per cent. of all cases operated, improvement in 24 per cent., and no improvement in 8 per cent. The largest percentage of cure has been among those cases in which arthritic symptoms predominated: Cured, 76.4 per cent.; improved, 23.6 per cent. His experience with drainage of the seminal vesicles in patients suffering from arthropathies seems to indicate that the amount of relief to be expected in any given case will largely depend on the length of time elapsed between the acute urethral infection, the appearance of the joint lesion, and the operation for drainage. After ankylosis from fibrous or bony changes has taken place, operation upon the vesicles will offer but little except toward arresting further joint destruction.

102. **Treatment of Osteomyelitis.**—In 72 of the 82 cases analyzed by Simmons the age at onset was under 20 and in 58, or 70.8 per cent., under 15. If the diagnosis is made at the onset of the disease and the bone operated on at once, the prognosis is good except in the most severe cases of staphylococcic septicemia. This septicemia can evidently exist in what may be termed a latent state for a long time. In children with pain in a limb and evidence of toxemia, always consider osteomyelitis. Operate early even if the symptoms are rather vague. If the diagnosis is incorrect practically no harm is done while if correct a great deal of suffering may be avoided. In acute cases, open to medulla and pack the wound. Prognosis good. The treatment and prognosis varies of necessity somewhat in these early cases but in general the earlier the operation the better the prognosis. In cases in which the bone destruction has taken place, seen less than three months after the onset of the disease, perform subperiosteal resection when possible. Prognosis good.

In chronic cases of bone abscess of less than one year's duration, drain and pack. Prognosis good. In chronic cases with bone destruction of less than one year's duration, remove sequestrum and pack. Prognosis good. In old chronic cases, either with bone destruction or of the bone-abscess type, remove necrotic areas and drain. Try to obliterate the cavity with flaps of living tissue. If this cannot be done either use bone wax, pack or sterilize the cavity, allow it to fill with blood clot, and close without drainage. The prognosis, if the cavity can be obliterated, is fair, otherwise poor. The treatment when such bones as the pelvis are involved is unsatisfactory and the prognosis problematical. When in old chronic cases the whole shaft of a long bone is badly diseased the possibility of resection of the entire shaft with bone transplantation should be considered before amputation is resorted to.

103. **Intestinal Stasis.**—The victim of what Moynihan calls "Lane's disease" is easily recognized, and the symptoms are caused to disappear by appropriate surgical treatment. The patient is generally a woman of unhealthy aspect and attenuated figure. She is lean, cadaverous, flat-chested, and she has a sour breath and cold and clammy hands. The skin is harsh and of an earthy color and bears many crops of pimples; its secretion is apt to be distressingly noticeable. She makes complaint of "indigestion," pain after meals, flatulence, and inveterate and incoercible constipation. The abdominal muscles lack bulk and tone. They are flabby and flaccid, and all the viscera which they should hold up are fallen in greater or less degree. Mentally, there is often

a complete absence of the joy of life; the patient is a morose, querulous, and often suspicious and introspective person. These attributes are rarely all present together, but so many of them may coexist as to enable a distinct type of patient to be recognized. In the very obvious cases of this kind, Moynihan does not think the mild measures that can often usefully be employed for the novice—massage, abdominal exercises, and the unrestricted use of paraffin—are really of any value. These sufferers are properly cases for surgical treatment. The colon should be excised in whole or in part. In some, perhaps, ileosigmoidostomy may be done; but in every case, with one exception, in his own series there has been some regurgitation of the intestinal contents upward along the descending colon to the cecum. The stasis then is worse than before, for a mass of fecal material that is never wholly dislodged is palpable at all times.

Personally, Moynihan believes that nothing short of colectomy offers a substantial chance of cure. The part of the gut that needs removal is he thinks, the last part of the ileum, the cecum, and the ascending colon. Accordingly, in such patients who need surgery he prefers to do Friedrich's operation of resection of these parts of the bowel. The evidence at the moment available allows us to say that intestinal stasis does seem to stand in a causal relationship toward some cases of chronic joint affections, and that such cases exhibit a marked and instantaneous delay or even cessation in the destructive processes, after operation on the bowel and that a complete recovery of the joint ultimately occurs.

104. **Treatment of Second Degree of Pelvic Contraction.**—As to the treatment of the second degree of pelvic contraction, pubiotomy is Jellett's operation of choice, unless there are special circumstances in the case or special complications present. He says that pubiotomy is especially indicated in the young multipara, because of the effect of the operation on subsequent pregnancies, and because owing to previous labor, the vaginal canal is dilated and lacerations are unlikely to occur. On the other hand, cesarean section is more suitable in the elderly primipara, because vaginal laceration is more likely to occur, and because it is unnecessary in her to take account of future pregnancies. Premature labor is only indicated under special conditions which render either of the foregoing operations impossible or inadmissible. Craniotomy is only permissible when the child is dead.

106. **Plastic Operations on Stomach.**—Beck records the following experiments: 1. The plastic formation of a new pylorus by a flap. The results operatively were good. 2. Implantation of the small intestine in place of resected pylorus. The fluoroscopic examination proved the absolutely good function of the implanted intestine and the examination of the specimen of the dog killed after weeks showed remarkable changes in epithelial structure, the epithelium of the jejunum growing similar to that of the stomach. 3. The use of an intestinal patch for the stomach defect in the small curvature. The defect healed beautifully and the dogs did well. 4. Resection of large part of the front wall of the stomach and filling of the defect with omentum only, without stitching the wall. All the dogs survived. Even a few days after the operation they were lively and ate well and the examination after even as short a time as one week, surely after five to six weeks, showed that the defect had dwindled to a small point and the omentum covered it up on the outside, forming a defense wall against perforation. 5. Excisions of portions of the stomach and implantation of neighboring flaps of the stomach, according to the well-known laws of plastic flaps. These experiments were all satisfactory.

108. **Intussusception.**—The anatomic condition that has attracted Cubbins' attention the most is the length of the mesentery of the terminal ileum and the fact that the descending colon in these cases also possesses a distinct mesentery.

In order to avoid recurrence of the intussusception Cubbins has used the following method: The ileum is brought parallel to the ascending colon and sutured to it with three to five catgut sutures. The cecum is fixed in the iliac fossa in some cases with another suture. The fact that as the two bowels are parallel and cannot intussuscept will be at once evident. The long mesentery of these bowels allows them to assume a horizontal position in the belly, and we therefore need not consider a kinking of the ileum.

112. Abstracted in The Journal, June 27, 1914, p. 2047.

114. **Acute Hemorrhagic Pancreatitis.**—A positive diagnosis of acute hemorrhagic pancreatitis cannot be made with absolute certainty, since we still lack a distinct pathognomonic sign for this disease. Laboratory aids, such as the Cammidge reaction and the Wohlgemuth diastase blood test are of no value in this condition. The most striking feature of this condition, clinically, is the evidence of peritoneal disturbance in the upper abdomen, the so-called "acute abdomen" which all surgeons agree is an indication for surgical interference; and acute hemorrhagic pancreatitis should always be borne in mind in such cases. When finding the peculiar odorless serosanguineous fluid and the small flecks of fat necrosis, it is direct and undoubted evidence of acute hemorrhagic pancreatitis. The best results are obtained in cases in which operation precedes the stage of necrosis of pus formation. Hence, early surgical intervention in all such cases will be rewarded by more frequent recoveries.

Linder's observation of the intense cyanosis of the distended small intestines, cyanosis, with the peculiar granular or gritty feel of the thickened great omentum, has helped him in many cases to recognize the condition at operation, and look to the pancreas at once as the cause of the trouble. This is of special value in cases of patients operated on for supposed intestinal obstruction. The abdomen opened, the condition should be looked for and recognized quickly. Then prompt and efficient drainage should be instituted, causing the patient as little shock as is compatible with good surgical technic.

117. **Silence of Renal Tuberculosis.**—Renal tuberculosis gives no local symptoms in a large percentage of cases. Its first manifestation may be hematuria or symptoms of its spread to the bladder. Gordon states that a history of gonorrhea or the finding of colon bacillus, staphylococci, or other pathologic micro-organisms in the urine in no way excludes the concurrent presence of tubercle bacilli. In fact, renal tuberculosis predisposes the urinary tract to other infections and the tubercle bacillus is usually reinforced by such allies before it has progressed far in its invasion. It is usually unilateral at first, when the whole focus can be removed and the patient cured, but in time may become bilateral or miliary when the case is hopeless.

120. **New Operation for Stricture of Rectum and Sigmoid.**—By forcing the bowel downward toward the anus from within the abdomen, while the assistant steadied the bougie from outside the anus Wiener was able to overcome the stricture. The rectum was "milked" over the bougie at the site of the stricture until the largest Wales bougie lay in the rectum above the former stricture. The bougie was allowed to remain in place and the abdomen was closed without drainage. Eighteen hours after operation the bougie was removed on account of pain. Convalescence was uninterrupted.

122. **New Method of Lateral Intestinal Anastomosis.**—The technic of Soresi's method is as follows: After the usual preparation of the intestines the two stumps which are to be anastomosed are brought in contact, the cut edges in opposite directions. A strand of any suture material, preferably silk, about 40 cm. long, on which two round needles have been threaded (the choice of the needles depends on the operator—the author always uses plain seamstress's needles No. 7), is used for a seroserous suture in the following manner: The suture is started midway between the two cut edges of the intestine, about 2 mm. from the attachment of the mesentery. One of the needles is used to start the suture and the stitches are taken toward one of the cut edges up to a distance of approximately 3 mm. from the same.

A like procedure is followed with the other needle in the opposite direction. The two ends of the thread are gently pulled apart, but are held parallel with the suture line to insure a perfect approximation of the serous surfaces. The ends are dropped temporarily, to be used later. With a pair of scissors the two stumps of the intestines are cut longitudinally and parallel to the seroserous suture, approximately 3 mm. from it. Two needles are threaded with one strand of chromic or iodized catgut No. 1. A suture intersecting the three coats is started just above opposite the joint of the beginning of the seroserous suture, and is continued completely around half way with each needle, until the intestine is completely closed. The two ends of the catgut are then tied with two knots—the first one being a surgical one—and the catgut is cut short. The two needles which had been used to start the seroserous suture are picked up and the two ends of the silk again pulled gently as described above. The suture is continued half way with each needle, until the two needles meet when the thread is tied and cut close. The completed anastomosis appears more like an end-to-end than a side-to-side anastomosis.

123. **Treatment of Undescended Testis.**—The inguinal canal is opened by Wölfer as in the Bassini operation for the cure of inguinal hernia. A pocket is then prepared in the scrotum by stretching the parts with the fingers and packing a large piece of gauze into this fossa, leaving it in position until the testis is prepared. The testis is then found. Usually it can be delivered by picking up and freeing the structures emitting from the internal ring—the remnant of the gubernaculum ligament—using gentle traction on them and pressure on the abdomen just above the inguinal region. The cord is then freed, separating the vas from the rest of the structures. The deep epigastric vessels, usually two veins and the artery, are freed by blunt dissection and held out of the way with a blunt hook. The transversalis fascia is then cut down to the pubes. The testis is drawn behind the deep epigastric vessels. The vas will now follow down behind Poupart's ligament. The structures which extend upward and outward are freed from the peritoneum and dealt with as in the Davison operation—pushed behind the bulge of the peritoneum. When by posterior displacement of the spermatic structures, sufficient length has been given the cord to allow the testis to be placed in the lower part of the scrotum, the gauze pack is removed from the scrotal fossa and the testis placed in the pocket prepared for it. In doing this operation three times, Wolfer has not found it necessary to fasten the testis in the scrotum aside from placing a catgut suture from the periosteum and tissues over the pubic spine to the inner border of Poupart's ligament; in other words, the testis is simply retained in the scrotum by obstructing the scrotal outlet.

127. **Case of Genito-Urinary Tuberculosis.**—In Anderson's case in freeing a growth from the common iliac vein, the vein tore and this necessitated ligation in two places, above and below the point of rupture. In closing the abdomen there was a marked venous oozing, which showed how readily the collateral circulation was established. So far as he has been able to search the literature, Anderson has never found a case reported in which the common iliac vein was ligated.

130. **How to Sharpen a Scalpel.**—A quantity of clean beef fat is rendered to common tallow, strained through fine cloth or canton flannel, and while in the melted state, carborundum powder, No. 1 F is stirred into the melted tallow to make a stiff paste. The mixture is then allowed to cool. To use the paste, simply spread freely on a smooth strop, lay the strop on a table, and draw the scalpel back and forth at right angles not diagonally. This absolutely solves the problem of a keen-edged knife. In cold weather if the paste is too stiff, add a drop or two of olive oil to the paste on the strop. To get an extremely smooth and keen edge to finish the sharpening a paste can be used of No. 2 F carborundum powder mixed in tallow.

2. **Cerebrospinal Fever in Camps and Barracks.**—In the outbreaks among the troops, Osler says, there have always been three strong predisposing factors: Overcrowding in camps or barracks, the cold winter weather, and muscular overexertion among young recruits. Two of these conditions have prevailed during the past three months. The weather has been atrocious and an enormous number of young recruits have been in active training. There has not been special overcrowding, but a great many men have been in tents, in the ordinary regulation form of which, nine men live in close contact, and he can testify from examination that the ventilation is not always good. It is this very intimate contact that seems to favor the communication of the disease. With fresh air, sunlight, and scrupulous personal cleanliness, the epidemics, as a rule, quickly subside.

Osler adds that stringent preventive measures have been taken—isolation of the sick, systematic examination of the contacts, and the disinfection of the nasopharynx of any carriers, which should suffice to limit the outbreaks. In a circular issued a year or two ago in the French army, Vincent recommends the following mixture, to be used five or six times a day as an inhalation: Iodin 12 gm., guaiacol 2 gm., thymol 35 centigrams, alcohol 200 gm., potassium iodid 6 gm. Disinfection of the pharynx is carried out by swabbing with a 3 to 5 per cent. solution of glycerin and iodin. In the recent Texas epidemic Sophian found that a spray composed of 1 per cent. hydrogen peroxid and 9 per cent. argyrol, destroyed the meningococcus quicker than any other measure.

8. **Employment of Ether in Surgical Therapeusis.**—The conditions in which Waterhouse uses ether as an antiseptic are the following: 1. Psoas and other tuberculous abscesses in which, after incision and flushing with normal saline solution, ether (1½ ounces was the maximum employed) was introduced into the abscess cavity and the incision sewed up without drainage. 2. Abscesses, the result of appendicitis, in which, after incision of the abscess, the margins of the wound were held open with retractors, and 1 ounce of ether was allowed to boil away in the abscess cavity. 3. Cases of gangrene or perforation of the appendix, in which the neighboring inflamed coils of intestine were washed with ether. 4. Compound fractures: In these cases the wound in the soft parts, the fractured ends of the bones and the torn medulla were freely washed with ether. In two of such cases the fracture was plated, with excellent result. 5. Carbuncles, in which ether was injected not only into the slough, but 3 or 4 drops were also injected at intervals of about 1 inch, into the subcutaneous tissue just outside the carbuncle.

6. Tuberculous glands: Ether—3 or 4 drops—was injected by means of a hypodermic syringe into every gland that was palpably enlarged. 7. Tuberculous synovitis of joints, especially the knee, wrist, elbow and ankle. In all these cases Bier's passive congestion was also employed. Here the best results were obtained in examples of tuberculous hydrops, first described by the author's old teacher, Professor König. 8. Septic wounds of the soft parts, in which ether surpasses, in Waterhouse's opinion, all other antiseptics. 9. Sinuses, which were filled with ether. 10. Cases of pyogenic osteomyelitis in which, after a gutter had been cut in the bone and all the infected medulla removed, the cavity was filled with ether, the incision in the soft parts being usually left unsutured. 11. Suppurating buboes, especially those due to chancroid (Ducrey's bacillus). Ether is also a perfect application to the chancroid itself. 12. In cases in which an incision had to be made through skin in a part in which asepsis is difficult to maintain—for example, in axilla or scrotum, or when the patient was very stout—wash the entire wound with ether prior to closing it.

23. **Embalmment of Septic Wounds.**—The following is the treatment recommended by Mencière. Successive washings of the wound with the three antiseptics after atypical operations when, as often, necessary. Embalmment of the wound (permanent dressing) with gauze wicks soaked in the solution, the formula of which will be found below. For three or four days wash again with the three antiseptics—mercuric chlorid, 1:1,000; phenol, 1:40; hydrogen peroxid, 1:3—after which, remembering the susceptibility of the cells, only wash with hydrogen peroxid 1:3 or 1:4 and again embalm. Repeat the dressing daily. Mencière says it is a mistake to advise that the dressings should not be removed. A wound which is closing up necessitates an intense phagocytosis, an irruption of white cells which clog the wound and which form a liquid which it is always best to evacuate in order to avoid resorption. It is for this reason, too, that one must not close the wounds, but drain them freely with glass drains. Embalmment of wounds thus, following the formula given further on, is a powerful antiseptic deadly to microbes but sparing the cells, calling forth the phagocytes and constituting a stimulant to the wound. It is the means with which Mencière has succeeded best after having tried nearly everything—formol, salicylic acid, tincture of iodin and iodin vapor itself.

He does not decry tincture of iodin employed for a first dressing, but this method cannot be repeated, for if it kills the microbes it also causes necrosis of cells and leaves a surface which is an excellent culture medium, but not a good defense. The Mencière formula is as follows: Solution *A*, iodoform, 10 gm.; guaiacol, 10 gm.; eucalyptol, 10 gm.; balsam of Peru, 30 gm.; ether, 100 gm., to be used to soak the wicks of gauze or to be injected into the sinuses with a Roux's syringe. If hydrogen peroxid is lacking, or if one is prodigal, solution *B* may be used for washing the wound before embalmment. Solution *B* differs from *A* only in the quantity of ether, which is 1,000 gm. instead of the 100 of solution *A*. In case of idiosyncrasy or intolerance after a few days treatment (which is exceptional) omit the iodoform from the formula.

27. **Administering Drugs in War.**—The method which Tunnicliffe has employed is to prescribe the drug to be given in a semisolid aromatic base and to close the mass in a collapsible tube such as is generally used to contain remedies for external application. By varying the composition of the base in glycerin, bismuth base, agar-agar, etc., all climatic conditions can be allowed for. With a given base the weight of a given length of jet is practically constant, and by this means an accurate dosage can be obtained. The medicinal creams the author has had made so far all have the same dose, namely, 1 linear inch of the exuded jet. An inch can easily be measured against the last joint of the thumb and can practically always be accurately guessed. As a constituent of the base Tunnicliffe prescribes some aromatic substance which promotes salivation and thus reflexly stimulates swallowing. He has prepared, for instance, a chlorodyne cream containing up to 30 minims to the inch and a morphin cream containing up to 2 grains to the inch. The inch of jet can be severed from the nozzle of the tube against the patient's teeth, or if he is more or less unconscious it can be dabbed off on the back of his tongue.

41 Treatment of Ocular Tuberculosis with Tuberculins plus Antituberculosis Serum. A. Darier.

31. **Seton for Path of Bullet.**—Jousseaume here relates an old experience of his. He ran the end of a roll of tape through the passage tunneled through a patient's shoulder by a bullet. The roll of tape was kept protected, and the outer end was pulled farther through each day and cut off. The tape brought with it the pus and foreign substances in the wound and recovery was soon complete.

32. **Passive Ischemia in Prophylaxis and Treatment of Freezing Injuries.**—Debat has witnessed remarkable benefit from the measure described in these columns Feb. 13, 1915, p. 622, abst. 44. It is known as Jacquet's biokinetic method, and it wards off threatened freezing and helps to cure the consequences when the limb has been frozen. The intense vasoconstriction induced by the cold is counteracted by massage and exercise, the patient lying on his back and raising the leg perpendicularly, holding it in this position with both hands. The toes and ankle are worked vigorously and fast. This is kept up for five minutes and repeated every hour.

In the intervals the man reclines with the foot slightly elevated.

37. **Operative Treatment of Bullet or Shell Wounds of Nerves.**—Delorme has applied in ninety cases various operative measures, as he describes in detail with twenty illustrations. He declares that the suture of certain nerves is as delicate a procedure as the making of jewelry, but that few surgical measures give such gratifying results. Proper operative treatment requires the cooperation of the surgeon, a neurologist, an expert in electrotherapy and a physician skilled in histologic technic. He comments on the destructive lesions from bullet and shell injuries, so different from the clean cut of a stab wound. In treatment he seeks to cut away all the fibrous tissue interrupting the continuity of the nerve and thus produce a linear surgical cicatrix, loosening the nerve above and below far enough to permit coaptation of the stumps when the limb is placed in an attitude which relaxes the nerve. If the gap is too long to be thus bridged, a plastic operation should be done on the nerve. In cutting away the interposing cicatricial tissue he makes one transverse section after another, until sound tissue is reached, thus cutting off narrow slices and examining each in turn for sound nerve fibers. The various types of such injuries are discussed in turn and the special treatment for each. The immediate results have been good in his cases and there has been partial return of sensibility in a number; the interval since has been too brief for estimate of the ultimate outcome. The injury of the nerve had entailed persisting paralysis in all, rebellious to all medical measures, and there was already considerable atrophy.

39. **Prophylaxis of Gangrene.**—Quénu remarks that the conviction is becoming general that ample opening up of the wound is the main factor in warding off and treating gangrene in wounds. The aim is to permit free access of air to every part, not leaving a chink or crevice anywhere to serve as a nest for anaerobic germs. Hydrogen peroxid or cinchona powder are useful adjuvants and may prove all that is needed for superficial tunnels and small gangrenous wounds. For severe wounds, however, he scorches the tissues with air heated to 700 or 800 C. (1292 to 1472 F.). This transforms an exuding into a dry gangrene, and in several years' use of the apparatus he has found it of unfailing benefit. Since the war came on he has used it in twenty severe cases of gangrene from shrapnel wounds, and all his patients recovered except one who had gangrenous wounds in shoulder and hip and whose leg was completely gangrenous. The superheated air requires general anesthesia for its application, and it takes from fifteen to thirty minutes to do its work. The eschar that forms is very thin, as he has established by experimental research that the hot air does not char below the surface.

53. **Pyelitis.**—Posner comments on the comparatively recently established fact that the bacteria found in the diseased kidney pelvis are not exclusively those from the urinary passages below. This shows that the infection is not always of ascending but may be of blood-borne or metastatic origin, and this is of great importance for treatment. A true gonococcus pyelitis has scarcely ever been encountered; other germs are usually responsible for the inflammation, especially the colon bacillus. The blood-borne or metastatic origin of tuberculous processes in the kidneys has now been established beyond question, and the same must be accepted for the colon bacillus. C. Franke recently demonstrated an actual direct connection through the lymphatics between the colon and the right kidney which explains the preponderance of right pyelitis. The pediatrists have also recently called attention to the comparative frequency of bacteriuria following extreme constipation, while the lower urinary passages remain persistently normal. Bumm has recently reported a significant case; intestinal trouble developed after excessive ingestion of milk and pyelitis followed, both promptly subsiding as the milk was discontinued.

Posner believes that the pyelitis may be of ascending or of blood or lymph-borne origin, but regards the latter as more common. He has encountered cases in which the pyelitis dragged along for months or kept constantly recurring but healed promptly under daily rinsing out of the bladder with weak silver nitrate solution in addition to the usual general measures. The pyelitis may have been started by metastatic infection from the intestines, middle ear or other infectious process, but the pyelitis was kept alight by the secondary infection in the bladder and the muscular insufficiency on the part of the ureters. The stretching of the bladder in local treatment may by reflex action rouse the kidney pelvis to contract and thus expel its contents better. He relates a striking instance of this kind, showing the sequence of bowel trouble, pyelitis and, later, cystitis, and the cure of the chronically recurring pyelitis by treatment of the bladder alone. He mentions, parenthetically, the great benefit in some cases of pregnancy pyelitis, from systematic drainage of the kidney pelvis by catheterization of the ureter. Brongersma kept it up for 118 days, changing the catheter every eight or ten days, and thus enabling the pregnancy to be carried to term.

55. **Resection of Chest Wall in Treatment of Tuberculosis and Bronchiectasis.**—Zinn and Mühsam have had considerable experience with what they call extrapleural thoracoplastics, and here give an illustrated description of some of their seven surviving out of nine cases of empyema, and of the three surviving in the six bronchiectasis cases. The operation makes considerable demands on the patients' strength and there is much pain afterward. Sedatives to relieve this check the tendency to cough, and this in turn arrests expectoration and the stagnating secretions are liable to induce fever, especially in the bronchiectasis cases. The benefit finally realized, however, compensates, they declare, for all that has been gone through. The results with old empyema depend on the patient's recuperating powers, and hence the operation should not be delayed too long. In the five cases in which the operation was done to immobilize a tuberculous process in the lung, the results were most gratifying in four cases. The indications were for artificial

pneumothorax, but when adhesions prevent this, then the "extrapleural thoracoplastics" is the most available substitute for it, and frequently is followed by surprising improvement.

60. **Abdominal Wounds.**—Carl writes from his experience at a base hospital at Königsberg. The journey from the battlefield takes at least twenty hours, so that abdominal wounds receive absolutely conservative treatment, morphin to keep the bowel quiet, and not a drop to eat or drink for two days or longer. The lips are repeatedly moistened and 1,500 or 2,000 c.c. of a saline infusion is given daily. If no fresh blood oozes through the anus, saline is given by proctoclysis several times a day. The patient is kept on the same litter without changing to a bed, and he is not allowed to get up for two weeks, no matter how well he feels. Heat to the abdomen seems to hasten the processes of repair. The head of the couch is raised so the slope is as steep as the patient can bear. If there is nausea or eructation, the stomach is rinsed out. Among the 48 patients treated on these principles, only 23 developed peritonitis; 14 per cent. are ready to return to the front, and 38.75 per cent. died. Necropsy in the 18 fatal cases showed that conditions were beyond repair if an operation had been attempted.

66. **Improved Technic for Sterilization with Tincture of Iodin.**—Dedolph applies the tincture of iodin with an atomizer. The spray penetrates into every crevice, the fingers are not stained, there is no loss of the drug as when it is applied on cotton which is then thrown away. Another advantage is that the patient is spared the pain of contact as the wound is not touched except by the spray. Sloping and low, hidden surfaces can be reached better by the spray than by fluid.

67. **War Aneurysms.**—Bier has operated in less than two months in forty-four cases of aneurysm following a gunshot injury of a blood vessel. The walls of the sac are formed of fascia or muscle and clotted blood, the blood still circulating in the cavity left in the center. Some of the men had severe pain in the limb, edema and contractions; others had little disturbance except that the limb tired easily. Hemorrhage and infection compelled operative treatment in some of the cases, and in all the outcome was most excellent. The hole in the artery was exposed and sutured after the blood had been expelled from the limb down to the aneurysm but not below. The minutest injuries of the vessels below then become apparent by oozing of blood and can be attended to. In only comparatively few cases was it necessary to ligate the artery above and below the aneurysm.

69. **Metastasis of Furuncles.**—Riedel has encountered five cases of fatal thrombophlebitis in robust men, the consequence of a furuncle in the face or side of the neck in front. Another patient, a woman of 23, succumbed to thrombophlebitis from an apparently harmless pimple on the inside of her nostril. A man died from thrombophlebitis set up by a felon in the thumb. Riedel has also repeatedly witnessed thrombophlebitis develop from some injury of the forearm or fingers. The thrombophlebitis in all the preceding cases developed rapidly, especially when the veins of the face were involved.

Metastasis from a furuncle is more common, and it develops slowly and insidiously. Weeks, months or years may elapse before the metastasis becomes apparent. In his 54 cases of metastasis from a furuncle, carbuncle or felon, 13 of the patients died, a larger percentage than in his thrombophlebitis cases. All the 54 patients were otherwise healthy. In 14 cases the metastasis involved the bone, and in 6 of these was near the original focus. In 2 cases the vertebrae just below the furuncle developed the metastasis. In 5 cases metastasis was in the femur although the furuncle had been at a distant point. Three died of the 8 children among the 14 patients in this bone group. This fatality proportion corresponds to his experience with osteomyelitis in general. Of the 40 patients with metastasis in the soft parts only one was a child. In 3 cases metastasis was in the brain and proved fatal; in other cases it was in the eyes, thyroid, lung, epididymis, or muscles, all with favorable outcome. In one case it was in the thymus and proved fatal; 5 of the 14 patients with metastasis in the perirenal fat tissue, died as did also one patient with metastasis in the shoulder following a furuncle at the back of the neck. One robust man of 38 succumbed to a brain abscess seven years after a felon with metastasis at the back of the neck. He had complained of left headache nearly constantly since. It had been diagnosed "neurasthenic neuralgia" until he developed fever. An abscess in the temporal region was evacuated and a deeper one was found at necropsy.

Riedel's conclusions from these experiences emphasize the importance of treatment of every furuncle, as its consequences are incalculable. Superficial furuncles can be treated conservatively, merely shaving off the outer skin and covering and dressing thick with a salve to soften up and help the casting off of the plug. If infiltration develops rapidly and there is much pain, he advocates a crucial incision down through the plug after spraying with ether. The ether spray is not effectual unless the blood is expelled from the region. Deep-seated furuncles should be incised without any delay, and carbuncles should be cut out entire under general anesthesia. Petrolatum is not a good salve for furuncles; it dries out too soon. He prefers a salve with some resin in it, especially ointment of elemi.

72. **The "Twelve Commandments in Regard to Prevention of Crippling."**—A set of rules has been placarded broadcast throughout the hospitals in Germany and at the front. They impress the facts that repose is harmful for both joints and muscles, making joints stiff and muscles weak and emaciated; that time, trouble and expense will be saved by striving to ward off all disturbances in motor functioning, and by insisting on prompt orthopedic or mechanical after-treatment if such becomes necessary. "4. Shorten as much as possible the period when the joint is kept still; have it exercised as soon as possible and change its angle frequently. Keep up the strength in the muscles menaced by the enforced repose, having massage and electricity applied early and systematically, with active exercises. 5. Remember that the extensor muscles deteriorate faster than the flexors; pay special attention to the deltoid muscle in the arm and the quadriceps in

the knee, for the arm and leg can not be used properly if the extensors are weakened. 6. In immobilizing, place the shoulder, elbow, wrist, fingers, knee and other joints in the position most favorable for their functional use later," as is described for each in turn.

"7. Do not allow the hand to droop from its own weight when the arm is in a sling, as this favors stiffness of the fingers and prevents grasping movements. 8. Leave the fingers exposed so they can be worked freely, and warn the patient to keep them continuously working vigorously to ward off stiffness. Save enough of the hand to grasp things with if possible, as there is no feeling in an artificial hand, and it is thus decidedly inferior to even a mutilated stump that can still grasp articles. 9. Stimulate the circulation by exercising the legs and by deep breathing even when the man is unable to be up, as stimulating the circulation has a beneficial action throughout the body, promoting nutritional processes and repair in general. 10. Get rid of extravasated blood by measures to promote absorption, etc., such as raising the limb, massage, heat, alternating hot and cold douches, as blood coagulating in the tissues keeps up a constant irritation, entailing adhesions and binding together the tissues in the region involved. When connective-tissue adhesions develop, there is no possibility of absorption later. Remember that the circulation of blood and lymph is most sluggish toward the ends of the limbs, so that artificial aid is particularly required for extravasated blood in these regions." The last "commandment" warns not to disregard the mechanical factors involved, "for our motor apparatus is a marvellous mechanical apparatus, and only those who understand the mechanism of a machine and are good mechanics are able to start a complicated mechanical apparatus to work again."

74. **Urease Test for Urea in Blood.**—Hahn says that further experience has confirmed the precision and reliability of the soy bean urease test, applied to the urine according to the Hahn-Saphra technic. He also describes a simple method for determining the presence of urea in the blood or effusions with the soy bean urease; the alkalinity is determined by the iodin test. With the technic described, reliable results are obtained with very small amounts of blood and other fluids. No special apparatus is required and the findings with the test give an instructive insight into the retention of nitrogen in the blood, and are a means of estimating the functional capacity of the kidneys. Hahn says that it is unnecessary to use a precipitate of the soy bean ferment. A mechanically cleansed and dried soy bean flour with the fat removed answers every purpose.

Medizinische Klinik, Berlin

January 17, XI, No. 3, pp. 61-88

77 *Treatment of Fracture with Walking Extension. (Erfahrungen über die Behandlung von Schussknochenbrüchen mit Distractionsklammerverbänden.) P. T. L. Hackenbruch (Wiesbaden).

82 Present Status of Abortion. (Zum gegenwärtigen Stande der Abortfrage.) O. Rupp. Commenced in No. 2.
83 Treatment of Freezing Injuries. (Erfrierungen.) O. Nordmann.

77. **Extension Braces for Fractures.**—The standard for each end of the long brace is fastened solidly in the plaster cast; then by turning a nut in the center of the brace the ends are pushed apart as far as is needed. The extension can thus be regulated at any moment and the brace and cast are made light enough so the patient can walk around while the fractured bone is knitting together again, the ends held in proper place by the stretching of the segment of the limb. The article has eighteen illustrations showing the application of the brace to the arm, ankle, thigh and leg, and the correction of the displacement of the long bones realized with it. The joints above and below are left exposed to permit normal use of the limb. From almost the first the limb can be moved actively without pain, so that men with badly shattered long bones thus are able to be up and about. In treatment of the wounds in war the *Distractionsklammer* has proved remarkably convenient and efficient, surpassing Hackenbruch's highest anticipations.

79. **Bullet in the Pericardium.**—The young man had been shot in the second left interspace and had hemoptysis for a few days but there was no fever for nearly six weeks, merely signs of effusion in the pericardium. The operation the sixth week, when the temperature ran up, released a large amount of the sterile, blood-stained effusion and, when the trunk was raised, the bullet dropped down from where it had been lying on the right auricle. The pericardium was rinsed out with saline and some saline was left in it to prevent adhesions after suturing. Recovery was prompt. The heart had had to work for so many weeks hampered by the bullet, that slight hypertrophy and dilatation were left.

80. **Chlorosis.**—Von Jagic agrees with those who think that the basis of chlorosis is some constitutional anomaly analogous to the status hypoplasticus or lymphaticus. Girls without this constitutional predisposition may become anemic, debilitated, tuberculous or may starve, but they do not develop chlorosis. It is encountered as well among the well-to-do as in the working classes, but it is not so common as generally assumed, many cases being erroneously so labeled. This term should be restricted to true chlorosis which is a malady resulting from disturbances in the internal secretions of the genital organs and entails disturbances in blood production and especially in production of hemoglobin. It demonstrates the close connection between the internal secretion of the ovaries and blood production. The interaction of all the ductless glands is also probably a factor in chlorosis. In the Abderhalden test, ovarian and uterus substance is digested in chlorosis.

Menstruation is not normal in girls with chlorosis. Von Noorden found deficient menstruation in 77.2 per cent. of his cases of chlorosis. Von Jagic goes so far as to maintain that normal conditions in regard to menstruation practically exclude chlorosis. The primary and secondary sexual characters ripen early with chlorosis; the breasts are well developed as a rule, possibly a trifle too full. Low hemoglobin percentage may accompany unusually large numbers of red cells, but in chlorosis the color index is unusually low. This latter may be the case even when the reds are increasing under iron and the hemoglobin percentage is normal. Absolute lymphocytosis may be encountered, especially when the thyroid is involved. Lymphocytosis, and particularly mononucleosis, must be regarded as one of the signs of physical inferiority, particularly in persons of the hypoplastic type. Another frequent finding in chlorosis is the high position of the diaphragm; even when reclining the respiration is shallow, the diaphragm not making properly deep excursions on account of the infantile position of the ribs. The constitutional inferiority may be manifested further by narrow blood vessels and vulnerable endocardium. Pronounced mitral defects are not uncommon in women who have passed through severe chlorosis but with no history of serious infection at any time.

91 Wounds of the Eyes. B. Fleischer.
92 *Suture of Nerves. (Zur Frage der Nervennaht.) W. Spielmeyer. Commenced in No. 2.

86. **Wounds of the Lungs in War.**—The various reports here given embrace well over 200 cases of gunshot injury of the lungs. All report that the outcome in the cases reaching the base hospitals was surprisingly good. Toenniessen found that the presence of the bullet in the thorax did not

seem to influence the clinical course. There was no abscess or gangrene in any of his 56 cases, and there has been nothing so far to indicate that tuberculous processes have flared up under the injury. Böttner noticed that the abdominal walls were rigid in four of his thirty cases, although the bullet had passed through the chest alone. Conservative measures were almost always applied as, according to Ritter, it was found that even when the soft parts around the entering bullet hole showed severe infection yet the chest within was not infected, as a rule. Repeated puncture of the pleura confirmed this. When the fluid in the pleura showed infection, no time was lost in clearing out the fluid and extravasated blood. Gas gangrene of the lungs calls for immediate excision; in one such case emphysema in the neck was the first sign of the gas gangrene in the lung below.

92. **Suture of Nerves.**—Spielmeyer emphasizes that the central stump of a nerve long retains its capacity to sprout new fibers, and consequently that it is of little moment when the nerve is sutured during the first four or six months after the injury. The prognosis depends more on the location and extent of the injury, the peripheral nerves having a greater proliferating power than those more centrally located. The general health is an important factor in the outcome. Some typical bullet injuries of nerves are illustrated. They show among other things that even when a bullet has not completely severed the nerve, the bridge left suffers from contusion and extravasated blood and the cicatricial tissue that forms is too compact for the sprouting nerve fibers to penetrate. They are turned aside and the continuity of the nerve is not likely to be restored without operative intervention.

Wiener klinische Wochenschrift, Vienna

January 21, XXVIII, No. 3, pp. 57-84

93 *Infections with Bacteria of Paratyphoid Group. A. Heigel.
94 Tetanus. (Zur Prognose und Therapie des Wundstarrkrampfes.) O. Chiari.
95 *Positive Wassermann Reaction in Pemphigus. M. Hesse.
96 Vaccine Therapy of Typhoid. (Bakteriotherapie des Typhus abdominalis.) S. Mazza.

93. **Bacteria of the Paratyphoid Group.**—Heigel found signs of an acute catarrhal enteritis at necropsy of a two-weeks infant succumbing to umbilical sepsis, and he cultivated from the bowel tissues a bacillus similar to paratyphoid bacilli only that it did not agglutinate with these and that the indol reaction was positive as also fermentation of sugar. He has also cultivated a paratyphoid bacillus from an abscess in the liver of a woman dying of cancer at the papilla of Vater. This bacillus differed from ordinary paratyphoid bacilli and Gaertner's bacterium only by the absence of agglutination. He knows of no other instance on record of a liver abscess apparently exclusively the work of paratyphoid bacilli. The communication issues from the Institute of Pathologic Anatomy at Prague, but the writer fell in battle November 3.

95. **The Wassermann Reaction in Pemphigus.**—Hesse calls attention to the pronounced response to the Wassermann test he obtained in nine of eleven cases of pemphigus. With one exception there was nothing to indicate syphilis in any case.

97 Dislocation and Fracture of Upper End of the Fibula with the Tibia Intact. (Verrenkungsbruch des oberen Schienbeinendes mit Erhaltung des Wadenbeins: Eine typische Verletzung.) H. Riedl.

January 23, No. 4, pp. 49-64

98 *Symptoms and Treatment of Fracture of the Patella. F. Schultze.

98. **Fracture of the Patella.**—Schultze declares that there never is any diastasis with fracture of the patella unless the quadriceps is ruptured too. With this intact, even extreme flexion does not cause the parts of the broken bone to separate. The absence of diastasis therefore shows that the fracture of the patella is not accompanied by laceration of the stretching apparatus, and hence there is no need for operative intervention. If the extensor apparatus is torn, however, normal functioning can never be regained without an operation. A Roentgen picture of the knee in exaggerated flexion thus shows at once whether an operation is necessary or not.

Zentralblatt für Gynäkologie, Leipzig

January 16, XXXIX, No. 3, pp. 33-48

99 *Gynecologic Cholesterinemia Test. (Zur Bestimmung des Gesamtcholesterins im Blute an geburtshilflichen und gynäkologischen Fällen.) M. Huffmann.

January 23, No. 4, pp. 49-64

100 *Treatment of Pregnancy Kidney and Eclampsia. W. Gessner.

99. **The Cholesterin in the Blood During Pregnancy.**—Huffmann examined a large number of normal men and women to ascertain the normal cholesterin content of the blood, and then compared with this standard the findings in women at different periods during a pregnancy. It gradually increases during gestation, reaching its highest point in the last months, and then it drops to normal in eight or ten days, irrespective of lactation. The blood from the umbilical cord shows a low cholesterin content, regardless of the findings in the maternal blood. The maximum cholesterin content was found in eclampsia. It does not seem to vary with menstruation but rises during general anesthesia. It is low with cancer.

100. **Pregnancy Kidney and Eclampsia.**—Gessner queries whether these two conditions are the primary disturbance and the state of intoxication is a secondary phenomenon, or whether the reverse is the truth. He is inclined to think that the kidney disturbance is the primary trouble, and that this is the result of disturbance in the circulation in the kidney as it is pushed out of place by the enlarging uterus. A normal kidney yields readily and there is no disturbance, but if the adipose capsule is unusually thick or, for any other reason, the kidney is not freely movable and thus is unable to yield to the pressure from the enlarging uterus, there is traction on the pedicle, the circulation is interfered with and there is mischief at once. Neither in puerperal ischuria nor in pregnancy kidney nor eclampsia do the bladder and kidneys show any signs of inflammation; the disturbances all indicate merely impeded circulation through the organ. This disturbance in the circulation in the kidneys is the primary trouble, and this brings the intoxication in its train.

The logical conclusion is that in treatment of eclampsia the first thing is to relieve the traction or compression of the kidney, and the only way to do this promptly and effectually is to empty the uterus. Version should not be attempted as this impedes the circulation still more. If immediate delivery by the natural route is not practicable, then he urges extraperitoneal cesarean section according to O. Küstner, supplementing this technic by severing the vesicouterine ligaments which are the main factors in the traction on the urinary apparatus. By severing these ligaments this cuts the connections between the cervix and the neck of the bladder; even if the ligaments grow together again, they are liable to stretch more readily at subsequent pregnancies. With merely pregnancy kidney, no attempt should be made to sever these ligaments, as any manipulation of them is liable to interrupt the pregnancy. The kidney must be relieved from traction, however, and he advises cutting the ureter on that side and implanting the renal stump in the colon or appendix. This operation has often been successfully done when part of the ureter has been injured in some accident. As the traction is usually most severe on the right kidney, this should be the one first attacked. After all trouble is over, it is not a difficult matter to reunite the ureter stumps. He thinks this active treatment is much better than relying on keeping the patient under the influence of sedatives as with Stroganoff's prophylactic method, etc.

101. **Clinical Picture Masked by Swallowing of Air.**—Dozzi refers in particular to the cases in which some serious organic disturbance is heedlessly credited to "gas in the stomach," and thus the period for effectual treatment is allowed to slip past. The two affections in which this is most liable to occur are disease of the coronary arteries and latent ulcer in the stomach or duodenum. He relates a number of instances in which the disturbance from coronary mischief was assumed to be merely the discomfort from swallowed air. He cites the case of a prominent physician at Paris who died at 40 from this cause, his latent syphilis, the cause of the arterial trouble, ignored and hence untreated. With the Wassermann reaction we are better equipped now to detect syphilitic arterial trouble if the possibility is borne in mind that the disturbance may be more than mere discomfort from a habit of aerophagy. He has found that the swallowing of air may not only impede digestion but prevent proper utilization of drugs given by the mouth.

102. **Death Following Intraspinal Injection of Novocain.**—Scandola's patient was a priest, 69 years old, with signs of a mild myocarditis so that when a herniotomy was undertaken the lumbar route for anesthesia was chosen rather than that by inhalation, and only a small amount of the novocain solution was injected. The patient bore the operation well and seemed to be in the best of condition that night but the next day there was some delirium and signs of paresis of the intestines gradually became evident, with fatal outcome the third day. The euphoric delirium had continued all the time and necropsy showed that there were no signs of peritonitis. Merusel reported last year the death of two patients of 75 and 80 after intraspinal injection of a small dose of novocain. In several other elderly patients there was subdelirium, requiring constant surveillance, but the patients recovered after four or five days. Scandola has also had phenomena of collapse in an elderly patient who recovered finally under stimulants. The spinal nervous system seems from these and other data cited to be peculiarly susceptible in the elderly.

103. **Poisonings from Mercuric Chlorid in Italy.**—Sabbatani calls attention to the progressively increasing number of cases of fatal poisoning from mercuric chlorid in Italy in the last few years; 38 per cent. of the 4,993 cases of fatal poisoning, 1903-1912, were due to this drug. This number is below the actual facts, as probably the death from bichlorid poisoning was in some instances ascribed to other causes. Assuming that only one in three or four dies, the number of cases of poisoning would therefore total six or eight thousand in the ten years in question, to a population of about 33,000,000. The average of nearly a thousand cases a year has been much surpassed in the last two years. The number of suicides by this means has increased in fifteen years from 20 in 1899 to 309 in 1912. This great increase is seen by the statistics presented to coincide with the putting on the market of bichlorid tablets, rendering the purchase of the drug so easy. Sabbatani insists on the importance of prescribing very small quantities in ordering mercuric chlorid, so that the amount will all be used up soon and none of the tablets left over.

107. **Local Injections of Iodin in Treatment of Goiter.**—Tansini regrets that Luton's method of treating goiter has fallen into disuse as he thinks it deserves a better fate. He has had constantly excellent results from it, injecting the tincture of iodin directly into the interstitial or parenchymatous tissue of the goiter. It is indicated, he reiterates, only in the cases of follicular or parenchymatous goiter, that is, only in those in which the thyroid tissue approximates most closely to normal. The disrepute into which it has fallen is the result of applying the method to cystic or colloidal goiters, or those with vascular or fibrous changes; iodin does not act on vessel or fibrous tissue nor on degenerated tissues.

In order to exclude all such cases, Tansini makes an exploratory puncture in case of doubt. Operative measures are better in the mixed cases but sometimes he has found it possible to combine resection of part of the goiter with injection of iodin in the undegenerated regions. He injects a mixture of 20 parts tincture of iodin; 1 part potassium iodid, and 40 parts distilled water, making an interstitial injection of 1, 2 or 3 c.c. at a time, making two or three injections at different points during the same sitting. He repeats the injection at first every second day and then every third or fourth day or at longer intervals according to the size of the goiter. He has never had the goiter recur in any of his cases. The intervals since the treatment range from one to several years. The injections are only rarely painful and then there is merely slight pain for a few hours at the point of the injection.

123. **Hemolytic Jaundice.**—Biffis reports five cases in adults. In none were there any signs of cholemia, and bile pigments were never detected in the urine, but only large amounts of urobilin. The urobilinuria did not seem to parallel the anemia; even when the anemia progressed to a fatal termination, in Case 3, the urobilinuria did not increase. This suggests that the fatal outcome was due not so much to the destruction of the blood as to the lack of regeneration of the blood. The enlargement of the spleen was due to mere congestion in some of the cases. The most important feature of the disease is, he repeats, the paroxysmal attacks of destruction of blood corpuscles, the *crisi de deglobulizzazione*, as he calls them. In the acquired hemolytic icterus the jaundice is of little moment while the anemia is extreme; in the congenital type the reverse is the case. All agree that medical treatment is ineffectual in the acquired type except as repose and freedom from physical or mental stress wards off exacerbations. Biffis' unfavorable experiences with splenectomy in these cases suggest the necessity for considering well before undertaking it, bearing in mind that there is no record of splenectomy having cured the affection although considerable improvement has followed it in some cases on record.

125. **Transplantation of Rat Tumors.**—Mazza noticed among the other phenomena in his experimental research that the spleen was always hypertrophied in the rats with tumors. He also found that rats previously treated with human cancer tissue seemed to be refractory to inoculation of rat tumor tissue. He thinks this latter observation encourages the hope of effectual therapeutics in man along these lines.

128. **Myomas in the Stomach.**—Nassetti found smooth muscle tumors in the stomach at necropsy of seven cadavers, all but one were of males between 45 and 71; the female cadaver was of a woman of 56. The subjects had died of pulmonary tuberculosis, pneumonia, chronic enteritis, cirrhosis of the liver, arteriosclerosis or kidney stone trouble. There had been no symptoms to call attention to the stomach except hematemesis in the liver case, and here numerous varices in the esophagus might have been responsible for the vomited blood. He reviews the smooth muscle tumors in the stomach on record, having compiled 140 such cases. In 95 cases the sex is mentioned, 37 men and 58 women. In 2 cases the subjects were boys and in 2 others girls between 10 and 20; one man and one woman between 20 and 30; one man and 8 women between 30 and 40, and 5 men and 13 women between 40 and 50. No correlation was evident between the tumors and the clinical condition of the subjects. Gastric ulcer was mentioned in only 4 cases, and in some there had been a long interval between the cure of the ulcer and the discovery of the myoma. The article is to be continued.

132. **Loose Bodies in Joint.**—Boks relates that the discovery of two "joint mice" in one knee of a patient started a systematic investigation of the joints of all the cadavers he had occasion to examine. He also studied the literature on the subject. In his case the man of 74 was being treated for a gonorrheal stricture when he called attention to chronic pain and discomfort in his left knee. It was evidently the seat of a deforming arthritis, but two loose bodies were found in it. The microscope showed that the loose bodies did not show the changes of deforming arthritis, evident in the joint itself. There was a history of a contusion of this knee thirty-five years before. This probably induced an infectious process and casting off of the two scraps of bone and cartilage. Their presence in the joint or other causes started later the deforming arthritis. No other joint was affected. He thinks this case throws considerable light on "joint mice" in general as there was no evidence of proliferation of new bone but merely of hyaline cartilage tissue, alike in structure in both.

133. **Treatment of Delirium Tremens.**—Theunissen compares the mortality with delirium tremens in his service in the last six years—2 per cent. of 120 cases—with Kraepelin's reported mortality of 3 or 4 per cent., Bonhoeffer and Ziehen's 9 or 10 per cent., while Ganser has had only 1 per cent. In his own 2 fatal cases, death was due to extraneous circumstances, so that his record in reality is exceptionally good. He ascribes this to the method of treatment which consists essentially in the closest watching over the patient, looking out for a relapse or a tendency to suicide. The patient is not kept alone in a separate room unless absolutely necessary. The diet is abundant but preferably milk alone. Sedatives are given as required, and stimulants are given at the end when there is anything in the previous history to suggest danger on the part of the heart. The experiences to date with treatment on these principles have been very gratifying. The sedatives found most satisfactory are paraldehyd or amylene hydrate, either internally or by the rectum. In the two fatal cases hyoscin had been given instead. Paraldehyd acts quickly, and Theunissen states that no cases of poisoning from it are known. Even when 100 or 150 gm. have been taken with suicidal intent, the result was merely prolonged slumber without disagreeable by-effects. He has observed nothing to suggest the alleged unfavorable influence on the aorta. His experience has shown further that protracted baths are not needed in treatment of delirium tremens.

136. **Serodiagnosis of Tuberculosis.**—Hekman has worked out a method with stained tissues and stained horse fibrin which, he declares, gives promise of a technic for serodiagnosis more sensitive than the Abderhalden dialysis method. He stains the horse fibrin or human lung or kidney tissue with an aqueous solution of methylene blue or eosin, leaving it in the stain for sixteen hours and then getting rid of the superfluous stain by boiling in constantly renewed water until the water ceases to show a trace of the stain. Fibrin thus prepared can be kept in salt solution or water without giving up any of its stain. But if human serum is brought in contact with the stained fibrin the latter is digested and the fluid becomes tinted with the stain. The serum of every human being contains this substance which is able to digest stained horse serum, lung or kidney tissue, but the intensity of the action varies in different persons. No law governing this variation has yet been discovered except that the serum from persons with chronic kidney disease always digests stained kidney tissue with special energy.

The digestion of stained fibrin can be inhibited by addition of tuberculin. The fibrolytic process can also be inhibited by addition of unstained albumin or kidney tissue. When the stained fibrin is being acted on by tuberculous serum, and tuberculin is added to inhibit the fibrolysis, the inhibition is much less pronounced than when the serum used comes from a non-tuberculous subject. This is the basis of the method as applied to serodiagnosis. The figure representing the limit of dilution of the serum with which there is no further digestion of the stained fibrin, is divided by the figure representing the dilution of the serum with which the added tuberculin completely inhibits the digestion of the fibrin. The quotient of these two figures is the index for this method of serodiagnosis. The index is thus characteristically lower in the tuberculous than in non-tuberculous cases.

137. **Pregnancy and Pulmonary Tuberculosis.**—This article is a brief summary of the data supplied by 155 physicians in the Netherlands who filled out question-blanks asking for their experience with regard to the influence of a pregnancy on pulmonary tuberculosis. The detailed report is to be

published in full in a Dutch gynecologic journal and it is announced that a reprint will be sent on request to Prof. B. J. Kouwer, Utrecht. Among the question blanks filled out and returned, 54 physicians reported constantly unfavorable experiences and 27 exclusively favorable. In the 35 cases of laryngeal tuberculosis, 10 of the women survived with the pregnancy carried to normal delivery, and of the children of the 25 women with severe laryngeal tuberculosis, 7 are living. Of the total 407 cases of pregnancy in tuberculous women, the disease is said to have been aggravated in 184, while no harmful influence was apparent in 223 cases. In 192 cases the tuberculous women passed through more than one pregnancy; 56 of them died of their tuberculosis. Among these one-fifth succumbed to acute miliary tuberculosis and one-ninth in the fortnight after delivery. Many of the women passed comparatively unharmed through various complications of the pregnancy, uncontrollable vomiting, hydramnion, pregnancy nephritis, premature separation of the placenta, puerperal fever, etc., revealing remarkable resisting powers. On the whole, the results of the inquiry justify a stand against the prevailing pessimism in regard to the influence of pregnancy on pulmonary tuberculosis. The pregnant tuberculous woman needs, of course, good care, repose, nourishing food, etc.

141 *Curability of Gonorrheal Vulvovaginitis in Little Girls. (Om Prognosen for Vulvovaginitis gon. infantum.) B. Pontoppidan.

141. **Prognosis of Gonorrheal Vulvovaginitis in Little Girls.**—Pontoppidan states that in 779 cases of this kind at a Copenhagen hospital, since 1896, there were complications in 6.8 per cent. He has reexamined about 22 per cent. of the cases since 1907. In 8 of these 79 patients gonococci had been still present when the patients had been discharged from the hospital, but recurrence was known in only 2 instances. All the others seem to be clinically cured. Treatment was by local application of silver nitrate and other silver salts, the concentration varying with the age of the child. In his experience, infection occurred usually about the age of 2 and treatment required several months. In certain cases exacerbations and remissions kept up for several years but the final result seems to be a complete cure so that there is little if any danger of the affection dragging along into adult life.

148 Annular Erythema; Seven Cases in Short Period in One Family. (Annulat Erytem med epidemisk Optræden.) A. L. Fønss.

144. **Injury from Light.**—Fønss discusses the nature of the rays which cause erythema, and relates the experiments by Finsen and others which have thrown light on this subject. The action of sunlight on the normal skin and eyes and of light reflected from the snow is compared with their action on the abnormally reacting skin, especially in hydroa vacciniformis, variola, pellagra, xeroderma pigmentosum, solar eczema and Hutchinson's prurigo. Fønss has encountered one case of hydroa vacciniformis. The patient was a woman of 23 otherwise healthy; her skin affection first developed at the age of 8 and affected the hands, arms and face during the spring and summer, subsiding in the fall. The intensity grew less after the age of 15 but is still quite marked in the spring, the vacciniform aspect still typical. Hematoporphyrin is sometimes found in the urine.

He has also encountered four cases of xeroderma pigmentosum. The patients were a child of 9, a young man and a young woman and a woman of 41. In the latter case the affection is of thirty-five years' standing; no tumors have developed at any point, merely the typical pigmented patches, enlargement of the veins and atrophy of portions of the skin. In the other cases there were ulcerating tumors. The affection began in early childhood in the young man and at 19 there were nine ulcerations on the face and neck. The microscope showed that one was a carcinoma, the others rodent ulcers. In discussing injury from artificial light, Fønss relates the case of a young woman who worked under a mercury vapor light in copying photographs, and developed severe dermatitis on face and hands; there was only slight conjunctivitis although the eyes had not been protected.

146. **Elliot's Operation for Glaucoma.**—Lundsgaard concludes from his experience with this operation on forty eyes that it is a valuable addition to our methods of treating glaucoma, relatively certain in its effect in suitable cases, and easy to do. But there are certain dangers connected with it, which forbid its general application, especially in prophylaxis alone. Of course the earlier the operation is done the better the results, but he has witnessed several cases in which the abnormal tension in the eyeball subsided apparently spontaneously or under application of myotics, and there has been no recurrence of the tendency to glaucoma. The tension in these cases was never very high, never over 30 or 35, so that now, in cases of this type, he waits a while to see if they will not return spontaneously to normal. When the pressure is above 30 mm. and does not subside under myotics, he operates at once in all cases of simple glaucoma, even when the field of vision and visual acuity are not considerably reduced. He has never noted any aggravation afterward in such cases. With secondary glaucoma, he prefers iridectomy. The outcome of Elliot's operation was ideal in thirty-two of the forty eyes, the interval since ranging from six months to two years. In two others, both with cyclitis, there was detachment of the retina with atrophy of the eyeball, and in six the tension in the eyeball persisted unmodified. In all but one of the eight cases there was preceding chronic inflammation.

147. **Injection of Paraffin in Treatment of Ozena.**—Blegvad reports five cured or materially improved over a period of two or three years out of thirty patients whom he has treated by local injections of paraffin. The interval since has been too short in some of the others to estimate the outcome, but the fetor has disappeared in practically all. The benefit is possibly from the narrowing of the lumen, enabling the nose to be blown more effectually and thus preventing accumulation of crusts, but the modification of conditions in the mucosa is probably the main factor. The mucosa is softened and rendered succulent by preliminary injection of water, so it takes up and holds more of the paraffin. The latter is injected beneath the mucosa on the inferior turbinate and septum. It lifts up the mucosa and then the paraffin is injected directly into the mucosa. There was moderate hemorrhage in one case and quite severe in another, coming on in the night afterward, but subsiding spontaneously. In two other cases there was brief suppuration in the septum. The ultimate outcome depends on the regenerating powers of the mucosa. He uses paraffin with a melting point at 51 C.

PAST AND PRESENT HEALTH METHODS IN LOUISIANA *

OSCAR DOWLING, M.D.
President of the Louisiana State Board of Health
NEW ORLEANS

Louisiana in every aspect of her history is unique; in the evolution of her health service no less so than in her political and social development. For many years, like Louis XIV, New Orleans thought and acted *"L'état, c'est moi"*; for her the state did not exist. Even yet, like many other cities, she is, where affairs of state are concerned, absurdly egoistic. For many reasons the attitude seemed logical, and in everything pertaining to disease especially so. Did not yellow fever and cholera attack the city first, always? Therefore, if money was to be spent in sanitation or protection, where should it be expended but there? If the city were free from pestilences, were not the people of the state safe? It was futile to argue a proposition so apparent. If the citizens of Louisiana outside of New Orleans thought at all on the subject they, too, concurred that it was from the city the inevitable epidemics spread; then why concern themselves with the lack of health supervision in the state?

As far back as 1797, an observing Creole gentleman is quoted as saying during the period of digging the Carondelet Canal, "in its neighborhood the fevers were awful, even with creoles." In 1811, 1817, 1819, 1822, 1832, 1833, 1837, 1848, 1849, 1850 and 1853, yellow fever and often cholera took their toll of human lives, sometimes few, sometimes thousands. During this period there were occasional boards of health continuing two or three years, with long intervals intervening. Having little authority or means, they were mere boards of record, and little benefit resulted from their efforts. In 1853, there was in existence one of these boards and, "the city council having adjourned for the summer," it appointed a sanitary commission to inquire into "the origin and mode of transmission or propagation of yellow fever; to inquire into the subjects of sewerage, common drains and quarantine, and to make an examination of the sanitary condition of the city." For the student of history the report of this commission is interesting reading. It was published in a volume of 560 pages, which one must have good eyesight to read. The conclusions as to the origin of yellow fever are ingeniously built up, but the recommendations of the commission read astonishingly like some of our own in the year of grace, 1914.

The decimating epidemic of 1853 moved the legislature to action and a new law was passed with an appropriation of $50,000 for erection of buildings and establishment of a more effective maritime quarantine. The "nine competent citizens" appointed to carry out these measures were selected because of their known zeal in favor of the strictest possible system of quarantine. From 1858 to 1873, though the records of these stormy political days were poorly kept and no one at any time was overzealous in the reporting of yellow fever, it was known that the disease claimed its victims every year. In 1878, there were 4,000 deaths and at least 25,000 cases, with a recurrence in 1879 not only in the city but in twenty-five other points in the state. Quarantine in all its details absorbed the funds and time of the Board of Health. Strife, disappointments, failures, honest effort to prove honest convictions, marked the days of the struggle. Finally, in 1885, a system evolved through many years' experience, the most effective yet, was put into operation.

Not until 1879 did there come an awakening as to the necessity for permanent organization of a health department. In the revision of the constitution in that year provision was made for a board of health which, to quote from a report, "began its labors with scant resources and with the quarantine buildings in a dilapidated condition." All members of this board were citizens of New Orleans, three appointed by the governor and four by the "common council" of the city. It was in no sense a state body.

In 1898 the constitution was again revised and, at last, after eighty-six years of statehood, the legislative body decreed that there should be a board of health with state functions. Where there was such dire need for this form of civic service, it does not seem credible that it could have been so long delayed.

The new board found itself without sufficient authority and gave its efforts to obtaining legislation for increased powers. It endeavored also to extend activities, but yellow fever and maritime quarantine still loomed large in the health horizon; they would not "down" and so in spite of itself, this board also walked in "trodden paths." However, when proof was clear that the mosquito was the transmitting agent of yellow fever, an educational campaign was planned and in 1905-'06 many lectures were given throughout the state. Epidemics of small-pox and typhoid diverted these efforts and after one season the educational feature languished.

The casual student of these annals is impressed with the slow growth of the service and the apparent lack of definite accomplishments; but to one who understands conditions and the temper of the people, another aspect is revealed. Once I had the pleasure of knowing a skilled engineer, a great man, who finished every narrative of experiences with the statement, "every project worth while takes its toll in human lives." It is the thought of Kipling expressed in the lines:

---

* *Read before the Æsculapian Club of Boston, Jan. 9, 1915.*

> "Lift ye the stone or cleave the wood, to make a path more fair or flat—
> Lo, it is black already with blood some son of Martha spilled for that.
> Not as a ladder from earth to heaven, not as an altar to any creed,
> But simple service, simply given, to his own kind, in their common need."

There had been presidents and members of these boards of health from the earliest days of the struggle who felt the obligation to do more than was done. With the broader outlook and additional knowledge of the nineties, presidents of the state board had recommended and urged the adoption of modern methods. Their efforts were unappreciated, unrecorded, but the "simple service simply given" made possible the dawn of a better day.

I have taken this much of your time to make clear one phase of the situation—the historical—to show that up to a recent date there was no organized health force at work on general problems; that for some years after provision was made for a state service, it seemed impossible to change the routine of former years. I must further trespass on your time, to bring out another aspect—the psychologic. It is traditional with us to keep in the realm of the subconscious many things, which, if allowed to come to the surface of conscious thought, would prove disquieting. We refuse with cheerful whole-heartedness to acknowledge civic shortcomings; in fact, we pride ourselves on being true to customs and habits—hygienic or otherwise—which have been handed down.

This attitude in the past was concrete in the feeling that insanitary conditions, infections, even an epidemic, should be kept secret. "Yellow jack" and commercial stagnation were synonymous. Every one knew the "fever" was present almost all the time, so why publish the fact? With present knowledge of the manner in which diseases are transmitted, it is hard for us fully to appreciate the feeling of loyalty which was the foundation of this mistaken policy.

In 1910, the State Board of Health was twelve years of age. It had made a tentative attempt to establish a new era; it had touched the life of a few communities in which epidemics had existed, but in the main, it had worked for necessary legal authority to straighten out the quarantine tangle.

It was in the fall of this year that the present board decided to break the barriers of tradition and become an active factor in the civic life of the people. It did not take genius or learning or special insight to know that instruction was the thing needful. Nor did it take much reflection to realize that the lessons must be carried into the home life of each individual.

To meet this, through the courtesy of two public-spirited railroad presidents, one rainy November morning there rolled out of New Orleans two cars filled with "health" exhibits, and scheduled to make a stop at every city, town, village and cross-roads in the state. It was a "free show"—there were beautiful specimens of the heart, lungs, brain, and other "innards"; models that worked; models that indicated how a dairy should be built, a market arranged; cases of food which warned the housewife what not to buy; and bottles of patent medicines with warning cards to catch the eye of victims. Infant, school and home hygiene, with disease prevention and health promotion were illustrated—and it was free.

The exhibits gave opportunity to be very hospitable —to invite the mayor to see the "show," assuming that he was interested in everything pertaining to the welfare of his community, and to suggest that it would be a pleasure to inspect his town and give it a "score"; the teacher was invited to bring the school and, if he desired, some one could talk to the children first so they would "see" more intelligently and in the meantime the schoolhouse and grounds could be inspected. No public official or physician was slighted; all were cordially invited. Those engaged in serving the public as food purveyors, or otherwise, were dealt with as public servants. Every dairy, slaughter house, market, bakery, every drug store, every general store, which had on its shelves medicines, every jail, courthouse and lockup, was visited and "scored." Every owner, manager, or official whose name went on the card was sent a letter which gave details and, if needed, recommendation for improvements. If the "score" was "bad," instructions were explicit with "time limit" and if "very bad" the orders were "shut up and clean up."

Every evening, often in the open air, motion pictures were given, free, and at the meeting the results of the day's inspections were read. Without comment, the record of a market was given in full. Here is a typical report of a restaurant:

> ——— restaurant, S. ———, proprietor, is generally insanitary; the kitchen is very bad; no screens and numerous flies around; very bad water-closet about 20 feet from kitchen door; back yard dirty. Ordered a general cleaning and place screened. If this is not done in a reasonable time this place also should be closed.

That there should be no criticism or discrimination, the condition of the town or village was given. Water-supply, sewerage system, closets, garbage and waste collection, and the condition of public buildings were noted and commented on. For example, I quote from a report to the mayor of a city and president of police jury of a parish, December 22, 1910:

> During two days I have visited 8 meat markets, as many restaurants, 9 dairies, 1 butcher pen (which I am told represents the condition of all others), 3 jails, 1 school and made a number of observations around the city.
>
> Many of your restaurants need a general cleaning, especially the kitchens. The bakeries need soap and water, with whitewash and more light.
>
> Of the 9 dairies visited not one would be entitled to a score of 20 (counting 100 for perfect). I was much impressed by the number of separators. One dairyman claimed he sold butter only, yet we found another dealer buying daily from him, and, of course, we can only conclude somebody is getting milk from which the cream has been removed. Go out and take a look at the dairies and decide for yourself whether or not you desire to continue the use of milk.
>
> One slaughter-pen visited was said to be an index to the others. If this is true conditions could not be worse. Your city council should pass an ordinance requiring a central abattoir and provide a meat inspector. Your meat markets would do fairly well if provided with a sufficient quantity of water to clean the instruments for cutting and handling the meats. We found one man skinning a cow in the market. This should not be tolerated. . . . Your theaters are not properly ventilated; we refer especially to the moving-picture shows.
>
> There are too many surface closets, and the work being done by your scavenger is distressingly defective. This should be changed so as to place the service under the supervision of your local board.

> The parish jail is bad in all respects with nothing to commend it, and we demand that the old structure be replaced by a new and modern prison, or the old one be thoroughly overhauled so as to make it meet the requirements. Your city prisons are, one very defective and the other a hundred years antiquated. Give them the necessary attention.
>
> The Central High School Building is full of decaying timber; the heat and ventilation are both bad; the privies are very bad; and duty to the schoolchildren and teachers demands that these buildings be placed under ban.
>
> Your health officials are underpaid. They are timid and afraid to urge the enforcement of laws, as the public will not uphold them.

In all reports no favoritism was shown, no personalities injected. It was assumed that the citizens had a right to know and wanted to be informed as to conditions in places where they purchased food, or in the buildings where their children went to school or worked.

This high-handed and unheard-of criticism of officials and others was a bolt from a clear sky. What was the Board of Health and who was its president that he could order coal oil poured over the sausage and steak because he found maggots in the ice-box and in the meat? "Cooking killed the maggots; they didn't hurt." One man, a baker, when told he needed a bath and a clean shirt, said, "Doc, it's a good thing you hit the right day; this is tub night and time for a clean shirt. I just have one a week." His good humor was typical. There was astonishment but little resentment. Many accepted inspection as an inconvenience to be endured, but as an experience that would not occur again. They did not then know our tenacity of purpose.

It did not take long for the story of these "outlandish doings" to get abroad and we were overwhelmed with invitations. No community wanted to be left out. Soap, hot water, the white-wash brush, the rake, the shovel, the hoe and the garbage cart were brought into requisition in honor of our arrival and many a little town prided itself on being clean until attention was called to shortcomings. One fine old gentleman, mayor of a village, on being complimented, said, "Well, Doctor, I have been cleaning for a week, but my God, man, you don't think I can keep it up?" It took seven months to make the trip, but it meant a "spring cleaning" which was for many communities a new experience.

It was not only those engaged in business involving health who were shocked at these "new-fangled" lessons in cleanliness and sanitation. Dear old gentlemen and ladies—and some not so old—who had accepted sickness as inevitable, a cross to be borne because sent by an all-wise Ruler, were outspoken in their conviction as to this new "gospel of health." Men had died and worms had eaten them since the day of Adam and here was a doctor with a "health" train who would have the people believe that for the sin of uncleanliness they suffered typhoid fever; that "whom the Lord loveth he chasteneth," when the milk is unsterilized.

Since 1911, the board has bought two cars—one for permanent exhibits, the other for administration office, laboratory, and living quarters. With exhibits better planned, grouped and more pertinent to the needs of the public, two other extended trips have been made over the state and many short ones, each with some definite purpose in view. "Does it pay?" is the question asked by every health officer interested in the welfare of his state. Let us analyze.

While some things of note have been accomplished, they are few as compared with what we hoped for. We have striven for improvement in essentials.

To refer to the historical again: Local units as far back as 1882 were empowered to organize boards of health. Later, in 1902-1904, a simpler mode of organization was enacted, but up to recent years there were few such boards. It is evident that such bodies must be formed and informed with the spirit of the work before much can be done, so we have bent our efforts in this direction. Out of 195 incorporated cities, towns and villages, 104 report duly qualified officers and nominally, at least, every one of the sixty-four parishes has an organized parish board of health. Scarcely a third of these bodies can be called dependable except in an emergency; this is logical since with three exceptions, not one has sufficient funds to attempt effective work.

The outlook is encouraging, however. In a number of parishes there is a willingness to combine budget items for health by the police jury and school board, and with this fund employ a whole-time health officer. There is approval, too, of the "Tech" plan endorsed by Professor Sedgwick, of having one officer serve a number of communities. The great obstacle to this form of cooperation in Louisiana as elsewhere is the unwillingness of the "ward boss" or the dominant political faction to lessen the number of officials even in the interest of improved public service. What we need in health administration more even than increased appropriations is freedom from political domination. There will never be effective service until this reform is wrought.

I shall not attempt a list of things done. It may not be out of place, however, to mention those which we have won by tenacious, if impatient insistence, and the help of the courts. The greatest of these was the establishment of the constitutionality of our regulations. The city of New Orleans joined with our enemies to prove we had no power over the city and that our Code was unconstitutional. The Supreme Court gave us a favorable ruling both as to legality and police power. It was said we could not enforce the wrapping of bread; that the mayor could not be made to screen the city markets; that the people would not stand for prohibition of the common drinking cup and the common towel; that hotels would not meet the requirements; and that the parishes in which courthouses and jails were condemned would not provide new buildings. The doubting Thomases failed in their estimate of public interest. They were wrong; the board was right and we have had public support in all these things.

Realizing, as all health officers do, the need and value of vital statistics, in 1911 an effort was made to put into operation a system of collection of these records. In the face of tradition, we made postmasters local registrars and I am happy to say, we are now on the high road to admission into the registration area. Through the Department of Public Health, we have been given the franking privilege for morbidity reports, and, during the year 1914, a good beginning has been made for complete returns. Syphilis, gonorrhea and chancroid have been added to the reportable list.

The supervision of milk has been extended to all portions of the state; the dairies now average one-third higher than in 1911, and we have reason to be grateful for the support given us by the dairymen and others engaged in the production and sale of food.

Among the amendments to our Code, there is one which we have as yet only promulgated. It sets forth the requirements relative to the doctor's office. The board has been censured for implying by this regulation that the physicians are derelict; but it grew out of observation, and when the time comes for action not a few physicians will be astonished at their "score."

Every year one special line of work is emphasized. In 1912-1913, as a preparation for further effort, we removed from general stores harmful drugs and many patent medicines; later, analyses were made of a large number of the most popular of these nostrums. Last June the legislature gave us a law which prohibits fraudulent advertising. Armed with this and our own records, in 1915 we shall enter into what may be a losing fight against this powerful enemy.

In the realm of the intangible, two things are clear—the people have been brought into touch with a service of which, heretofore, they knew nothing. There are thousands to-day to hundreds in 1910 who know what to do to get redress from dishonest and unscrupulous food purveyors; who know that the state has provided means of protection and who, in an emergency, write or telegraph for assistance. As proof of this, the volume of office correspondence has increased tenfold and the range of inquiries in like proportion. Even in the remote rural regions, the state Board of Health has become—it may be a club or a bone of contention—but certainly an entity.

A second gratifying result is the acceptance of the policy of publicity by an ever-increasing number. When reports were read at night meetings on the first tour of the car, there were hundreds who came to listen, doubting the wisdom of such drastic methods. They wanted to hear, every one did, but they were skeptical as to the outcome. To hold up the filthy condition of a market, they said, will ruin the business; to tell us the baker is not clean will cause him to lose customers; it is not fair. Now they say, "We have a right to know; let him clean up." More than this, they write us, "The stores do not keep their food products covered; dogs stay in the market; we find mice in the bread; the children use a common cup—why don't you come and prosecute 'somebody'?" Control of infection by isolation is not universally popular or understood, but no community now makes an effort to conceal the presence of a communicable disease. Is the change in the public mind worth while? We think it all-important as a foundation for an intelligent demand for better service.

Our policy of publicity has been heartily condemned and as cordially commended. We assume that publicity is due the people whose servants we are. The office records are open to any one at any time. Complaints, calls for assistance, reports, everything in the mail is open to the reporter. Sometimes we suffer because of the point of view or the haste of the headline editor, but the policy is sound. The press, whether adversely critical or otherwise, is our best friend and ally.

Public-health work in our section has all the complexities and perplexities found elsewhere, and, in addition, others which do not obtain in many portions of the United States. You have typhoid, tuberculosis, venereal diseases, infant mortality, insanity and faulty rural sanitation; so have we, but in addition we have hookworm and pellagra and—we have the negro. He is the most difficult problem and he is so because we will not acknowledge him to be such. During 1914 we made special surveys of negro neighborhoods in New Orleans and other cities; we sent a negro teacher and lecturer with a moving picture outfit into many remote districts and we gathered what statistics we could of the prevalence among them of tuberculosis and venereal diseases. These investigations give us pause, for they prove beyond doubt that the negro is, indeed, in matters of health, the white man's burden.

This desultory sketch would be incomplete if I did not touch on our work in its relation to the physician. A full analysis would carry us into a discussion of the present medical order with its inheritances and its possibilities—the practitioner and the specialist, the sanitarian and the physician-administrator—the old type and the new—those who fear and those who are filled with courage. On the tours of the state with the exhibit cars, physicians and health officers have been unvarying in their courtesy. They acknowledge the need of this work in their own communities, but many think it a hopeless task. They do not believe the public can be convinced except through the "process of the suns"; some feel that aggressive methods are not in keeping with the dignity of the followers of Aesculapius. There is the conservative shrug and the tolerant smile, but beneath this with many—is the spirit of "God speed you" and "may your enthusiasm last." A few, from the first, have been wholly sympathetic and helpful, but candor constrains me to add that by far the greater number have regarded the movement as a doubtful experiment. It is natural that the rural physician who has not the perspective of new lines of work, should hesitate to accept radical teachings of—a health officer; likewise, it is natural that men who have for many years jogged along in the even tenor of their way should not feel enthusiastic toward modern innovations and experiments. But the doctor is, I almost said, the noblest work of God. Whatever his limitations, he is foremost in every age in the ranks of those who sacrifice themselves for the good of mankind. I have faith that whether our work now is furthered or condemned, the future will make plain its purpose and its value.

In the turbulent days of her early history, Louisiana's health code consisted of a few simple rules. "Early coffee" will keep off "the miasma" was, I think, the most popular and certainly the advice which met with general acceptance. Some of the wise conservatives "shut doors and windows at sun down" and "breathed not the night air," but to this the pleasure-loving paid little heed. With the growth of trade the vessels at the gate were the enemy. Activities centered on this menace to peace and happiness, but the thoughts of men were widened and with their discoveries there came new light and a new régime. We were slow to accept, but I am hopeful that the day of deliverance from sanitary evils is at hand.

The Clinical Art.—We may never forget that what is termed the humanity of our profession relates not merely to kindness, gentleness and sympathy. Our duties must take note of the specially human characters and varied peculiarities of the individuals we treat. This concerns very largely the management of patients, a great clinical art and equipment. We begin our professional work by studying Nature in all her forms, and, as Charles Kingsley remarked, "if we do not know Nature we cannot know art."—Sir Dyce Duckworth, *The Lancet*, Nov. 28, 1914.

A STUDY OF REVERSAL OF THE CIRCULATION IN THE LOWER EXTREMITY

J. SHELTON HORSLEY, M.D.
RICHMOND, VA.

AND

R. H. WHITEHEAD, M.D.
UNIVERSITY, VA.

The operation for reversal of the circulation in the lower extremity, or arteriovenous anastomosis, began to receive attention soon after blood-vessel suturing was put on a stable basis by the work of Carrel and others a little more than a decade ago. Certain cases of gangrene of the foot and leg are caused by gradual occlusion of the arteries in the lower extremities. This is due to some form of arteritis in which the intima plays the most prominent part and the artery walls become so thick that complete occlusion may occur. As a rule, the veins are but slightly affected. The arterial current has been switched to the veins with the idea that the arterial blood pressure would force the valves in the veins, and arterial blood would reach the ultimate capillaries of the foot, so conveying nutrition to the tissues.

Complete reversal of circulation in the lower extremity, i. e., attaching cardiac end of artery to distal end of vein and distal end of artery to cardiac end of vein, can be of no practical importance, since the operation would be indicated only when there was such disease of the arteries as to occlude them completely or partially.

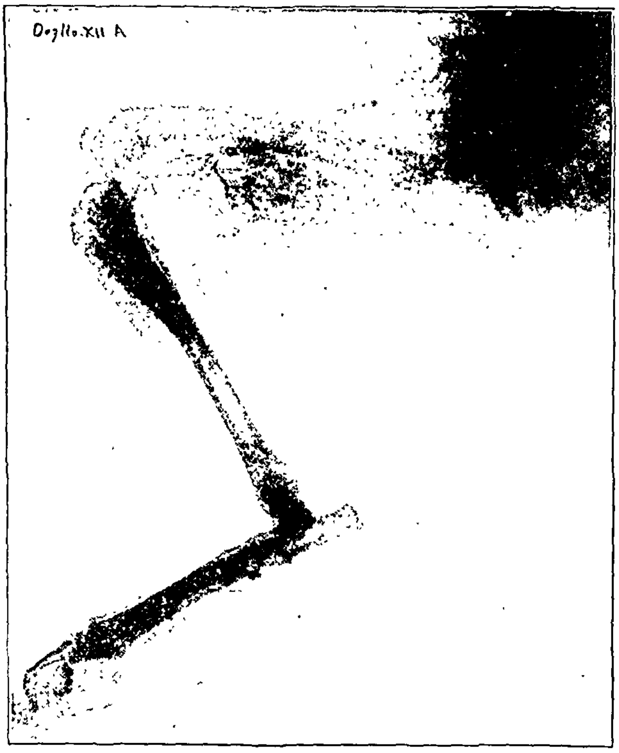

Fig. 1.—Cinnabar mass injected into the reversed circulation of Dog 12. The injection was made half an hour after operation. The roentgenogram shows that the cinnabar goes a little below the knee and returns toward the back part of the thigh in the direction of the branches of the iliac vein. In all of these roentgenograms the negatives were reversed when the photographs were printed, so the left extremity appears as the right.

A number of surgeons have done arteriovenous anastomosis with varying results. Among those who favor it are Carrel and Guthrie, Bernheim,[1] Wieting[2] and Goodman.[3] Wieting, whose experience has been quite extensive, asserts that the operation is clinically successful in his hands, though he admits that there are many questions which have not yet been settled. Bernheim is rather enthusiastic over the beneficial results obtained by reversing the circulation. Charles Goodman[3] reports a series of fourteen cases in which he reversed the circulation. In thirteen of these the end-to-end method was used and in one the side-to-side method. Of the fourteen operations, six were successful. Of eight cases in which failure occurred, including one death, one was a side-to-side, or lateral, anastomosis. Wieting used the intubation method nine times with two successes. Most of the operators, including Wieting, Bernheim, J. B. Murphy, and others, think that a lateral anastomosis with ligation of the vein on the cardiac side would be preferable to end-to-end anastomosis, as in this manner there are two channels instead of one, and the artery distal to the anastomosis is not put out of commission.

Carrel and Guthrie[4] reported experiments in reversal of the circulation, and conclude that reversal of the circulation in the limb of a dog is possible and that it can be established by an end-to-end arteriovenous anastomosis, but not by a lateral anastomosis. On the other hand, Coenen[5] of Breslau asserts that the operation is practically worthless clinically; that not all the valves give away; that the blood is shunted off through the first large anastomotic vein to the heart, and that the operation is wrong both anatomically and physiologically. Halstead and Vaughan,[6] after reviewing the literature and reporting cases, conclude that reversal of the circulation has little practical usefulness. They say:

> Up to the present writing there have been no means proposed of breaking down the resistance of the venous valves to the backward flow of blood, except by the action of the arterial current itself. It is also still a matter of doubt how much of the reversed current reaches the periphery in these cases, and how much is short-circuited, and what the individual variations are in the different cases. It is not even known for certain whether the femoral or saphenous vein, or their branches, will carry backward to the capillaries sufficient blood to maintain, unaided by the other vessels, that is, the collateral arteries, the circulation in the periphery of the limb. All these questions still remain to be determined by further experimentation.

In view of the greatly divergent views of prominent men, it has been puzzling to know just what therapeutic value can be attributed to reversal of the circulation in case of threatened gangrene through gradual occlusion of the artery. Undoubtedly, patients have improved after this operation when gangrene has not set in too promptly. Some operators have asserted that most patients have been benefited. On the contrary, patients operated on by other surgeons have not done so well. Frequently, it is stated that the line of demarcation of gangrene forms more quickly and that the stump seems to heal more promptly than would be expected if the reversal had not been done.

[6] Halstead and Vaughan: Surg., Gynec. and Obst., January, 1912.

We have not been convinced that reversal of the circulation was of undoubted therapeutic value, and though one of us (Horsley) has had several patients in whom it might have been done, the reports were so contradictory that he felt this operation was hardly justifiable. In an effort to throw some light on the subject, a series of experiments was undertaken with the view of establishing what became of the blood in the reversed vein. In order to prove that the reversal benefits by directly giving more nutrition, it must be established that (1) the arterial blood in the reversed vein reaches the ultimate capillaries of the foot. Obviously, no benefit can obtain by the arterial blood merely running a short distance in the main trunk of the vein. 2. Can the arterial blood in venous capillaries deliver its nourishment to the tissues? 3. If the arterial blood reaches the venous capillaries, how is it returned to the heart? All of these points are interesting, but two have the utmost clinical significance: first, whether the arterial blood ever reaches the ultimate venous capillaries in the foot, and second, whether it is capable of delivering nutrition from venous capillaries if it reaches them. If either of these two problems is decided in the negative, the operation naturally has no practical value. It was with a view of determining the first problem that the experiments here recorded were undertaken.

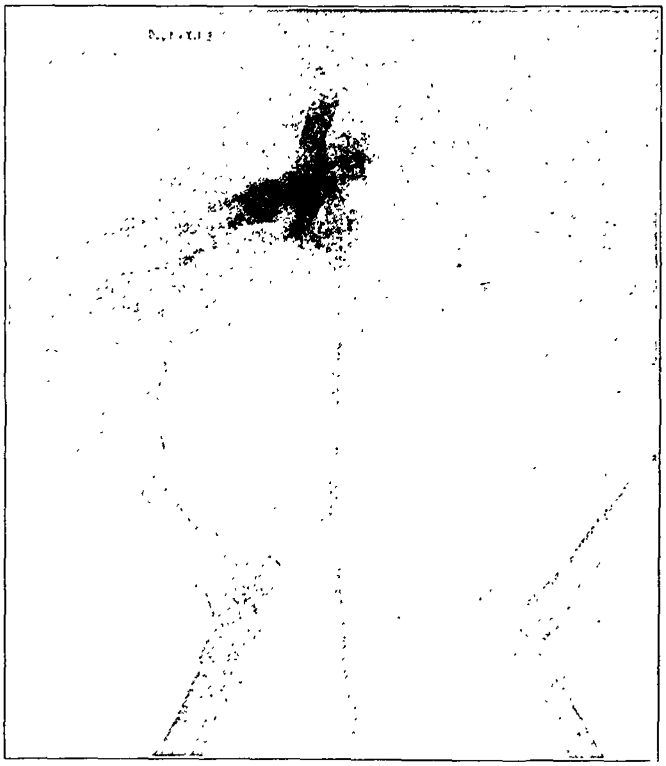

Fig. 2.—Both extremities of Dog 12 after injection of bismuth mass through the abdominal aorta. This injection was made immediately after Figure 1 was taken.

No more experiments were done than seemed necessary to prove the problem under investigation. All operations were performed under full anesthesia, and every effort was made to avoid inflicting pain.

Twelve operations were done by one of us (Horsley), all on the left lower extremity of dogs. The negatives were reversed in printing the photographs, so causing the left lower extremity to appear as the right. The anastomosis was done by the end-to-end method and cobbler's stitch, according to the technic already described.[7] This method secures broad surfaces of the intima in apposition and everts a flange. Its advantages are given in the literature mentioned.[7] While lateral anastomosis would be preferable, clinically, because it would not sacrifice the artery distal to the anastomosis, if attempted in a dog, objections might be raised that the artery of the dog is healthy, whereas in a patient with impending gangrene the arteries are partially occluded, and consequently the full force of the arterial blood stream in a dog would not be exerted on the vein, as most of the blood could be carried off through the normal, healthy artery. Injections in the vein of the cadaver would give but little information, as the enormous pressure from the syringe with its traumatizing effect could not be used in a patient. The end-to-end anastomosis delivers all of the arterial pressure into the vein, and creates the most favorable conditions for forcing its valves.

As a similar operation was done in each of the dogs, the central end of the artery being united to the distal end of the vein from one to two inches below Poupart's ligament, a detailed description of the operation in each instance is not necessary.

Of these twelve operations, two dogs died distinctly from sepsis. It is notoriously difficult, as has been pointed out by Watts and others, to secure aseptic healing in the femoral region of the dog, where infection from urine and feces is very liable to occur. In the later operations an effort was made to prevent this infection by closing the skin wound with catgut, fastening a small piece of gauze over the wound by means of six interrupted stitches through the skin, and fixing it with collodion. This dressing usually stays several days. It seemed to have some advantages, though two deaths from sepsis occurred when this method was used. Theoretically it is excellent; but practically, of the first two dogs in which this method was not used, one suppurated slightly, though the anastomosis was perfect, and the other healed primarily with occlusion at the site of anastomosis.

Five dogs were killed under ether, Nov. 27, 1914. They were Dogs 1, 2, 9, 11 and 12. Dog 8 died November 26 of some disease not connected in any way with the operation. He was injected and studied along with those that were killed. In Dog 2 there was complete occlusion at the site of operation. Dogs 7 and 5 died of sepsis, the surrounding tissue of the wound sloughing. In Dog 6 there was also marked suppuration and sepsis, though it did not seem to be sufficient to be the sole cause of death. Dogs 10, 3, 4 and 8 died of some condition not connected with the wound and which we called vaguely influenza. In all of these the post-mortem showed that the site of the anastomosis was patent and there was no thrombosis, except in Dog 3, in which a small white thrombus only partly occluded the lumen. In Dog 10, which died three days after operation, the leg was greatly swollen and congested with venous blood, though the site of the anastomosis was entirely clear. It was hoped that these dogs would live a sufficient length of time in order that they could be killed and the venous and arterial system drained of blood, which would afford much better conditions for subsequent injection. Consequently, none of the dogs that died from disease except Dog 8 was injected; but a post-mortem was held in order to determine the condition of the vessels at the site of operation.

---

[7] Horsley, J. Shelton: Surg., Gynec. and Obst., May, 1914. The technic is more fully described in a monograph by Horsley, entitled Surgery of the Blood-Vessels, St. Louis, C. V. Mosby & Co.

Analyzing the experiments from a technical point of view, we see that there were two deaths from sepsis and a third (Dog 6) in which sepsis played a prominent part and may have been responsible for the death. Of course, where the sloughing was extensive, the result was a failure. In two of these dogs the parts were so gangrenous that the vessels could hardly be recognized. Of the remaining nine dogs, seven operations were entirely and one partially successful, and there was only one complete failure (Dog 2). Two were operated on a short time before they were killed, one a half hour (Dog 12) and the other an hour and a half (Dog 11). As a rule, a thrombus, if it occurs, forms soon after the operation, and as there was no obstacle whatever to the injection, these anastomoses were evidently clear. But if only dogs that lived more than two days are counted, there are seven dogs with five completely and one partially successful result and one a failure. These results, if compared with end-to-end union in this region done by other methods, appear satisfactory.

Only five of the twelve dogs were injected, examined by Roentgen ray and dissected, for the reason that it was believed it was necessary to bleed them to death and leech out the blood with salt solution in order to secure a satisfactory injection. One animal (Dog 8), which died the day before the dogs were killed, was held over and injected, and there seemed but little difference so far as the Roentgen ray showed, between the injections in this dog and in those that were bled to death. In one of the five dogs that were bled (Dog 2), there was complete occlusion of the anastomosis; so these reports of reversal of the circulation are made from four dogs that were bled to death and leeched of blood by salt solution, and one dog that died from some extraneous cause not connected with the operation, probably from some form of influenza. Dogs 11 and 12 were injected an hour and a half and a half hour, respectively, after operation.

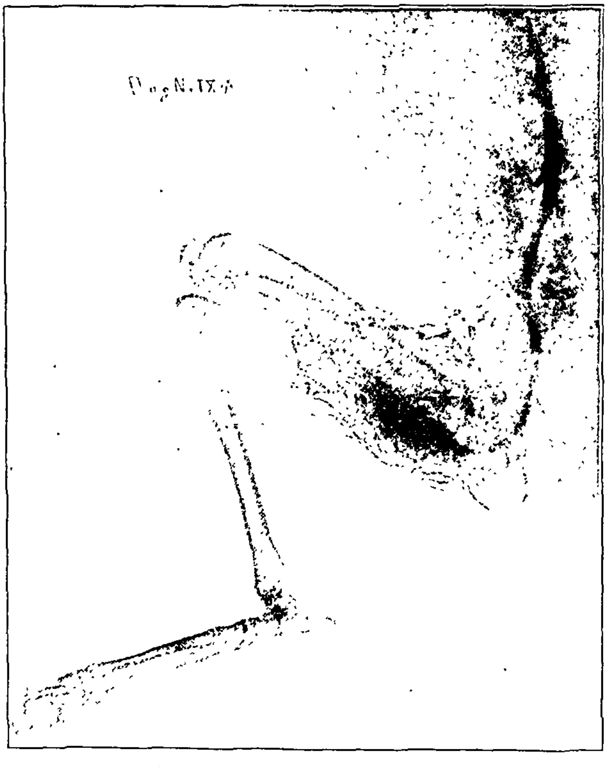

Fig. 3.—Cinnabar mass injected into the reversed circulation of Dog 9. Injection was made nine days after operation. The roentgenogram seems to show that the mass went at least no farther than in Dogs 11 or 12. Note cinnabar mass in vena cava.

The injections were made as follows: In a 10 per cent. solution of gelatin was mixed as much powdered cinnabar as would permit the mass to flow freely. This mass was injected while hot into the distal end of the femoral artery about an inch above its union with the femoral vein. The injection was made by gravity. The funnel was held about five feet above the level of the dog, the rubber tube being stripped with the fingers. The pressure must have been greater than the normal blood pressure of the dog, though no effort was made to measure it. In this way the mass might go even farther than the reversed arterial blood, because it may have broken down valves of veins under a pressure greater than the normal arterial blood pressure. It may be assumed that the pressure of the injection was at least equal to the normal blood pressure of the dog and was probably greater. The artery was tied after being injected.

A roentgenogram was taken of the left hind extremity, and the abdomen was opened and the distal portion of the abdominal aorta was injected with a 10 per cent. solution of gelatin in which as much bismuth was mixed as would permit the mass to flow freely. A second roentgenogram was then taken of both hind extremities, in order to contrast the normal circulation in the right extremity with that in the left.

PROTOCOLS (DISSECTION BY WHITEHEAD)

Dog 12.—The injection was made half an hour after completion of the operation. The femoral vein below the operation, and the saphenous, popliteal and recurrent tarsal veins were distended with the cinnabar mass as far as the level of the knee. Here the mass stopped abruptly and returned into the iliac veins through the deep femoral, internal pudendal, and gluteal veins by means of their anastomoses with branches of the veins below the site of the operation. The arteries throughout the limb were well injected with the bismuth mass.

Dog 11.—The injection was made an hour and a half after operation. No dissection was made, but the roentgenogram showed about the same condition as in Dog 12.

Dog 9.—The injection was made nine days after the operation. Here also the injection stopped abruptly at about the level of the knee, and returned to the veins above the site of operation chiefly through the channels noted in the case of Dog 12. In this dog, however, these return channels were considerably enlarged, appeared more numerous, and were distended with the injection mass. The distention was marked also in the iliac veins and in the inferior vena cava. The arteries were well injected.

Dog 8.—This dog died twenty-two days after the operation and was injected the following day. The cinnabar mass extended to the middle of the leg. The return channels throughout the thigh and upper half of the leg were apparently greatly increased in number, all the veins of the parts, both superficial and deep, being concerned in the process. They were markedly enlarged and tortuous, but their walls did not appear to be thickened. The arterial system was not well injected with bismuth below the site of operation, doubtless because of some technical error, as the arteries appeared quite normal, except that the deep femoral and the branches of the popliteal were somewhat enlarged when compared with the corresponding arteries of the opposite side.

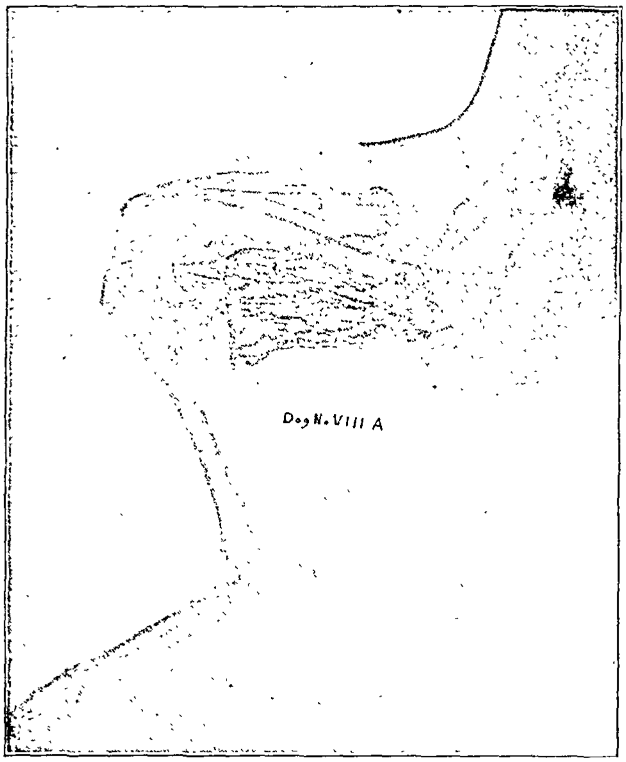

Fig. 4.—Cinnabar mass injected into the reversed circulation of Dog 8. The dog died twenty-two days after operation. It was preserved for twenty-four hours and then injected as in the other dogs. Note the very large collateral veins that conduct the mass easily to the iliac veins and the vena cava. Also note the cinnabar mass in the vena cava.

Dog 1.—Injection was made forty-six days after the operation. In this animal the venous injection reached the foot. The enlarged and tortuous condition of the venous branches, which was so marked in Dog 8, is not evident in the thigh, but is quite well marked in the leg. All the veins, however, both superficial and deep throughout the thigh and leg, contain the injection. The roentgenogram does not give a correct interpretation of the condition of these vessels; evidently the injection mass did not contain enough cinnabar to make solid shadows of all the veins. The branches of the deep femoral and popliteal arteries were enlarged, and extensive anastomoses between them, especially in the substance of the posterior femoral muscles, were evident; that is, an arterial collateral circulation had developed.

The Roentgen ray shows that in four (Dogs 12, 11, 9 and 8) of the five dogs, the injection mass reached only a short distance below the knee, and that it returned through the back part of the thigh and in the general direction of the branches of the iliac veins. In Dog 8 (twenty-two days) the vessels show enormous collateral venous circulation which apparently conducted the blood quickly into the branches of the iliac vein. In Dog 9 (nine days) and in Dog 1 (forty-six days), which were bled to death, the cinnabar flowed freely from the cut external jugular vein soon after the injection into the reversed circulation was started. According to the Roentgen ray, the cinnabar mass in the reversed circulation did not go far below the knee in any of these dogs except in Dog 1. In Dog 1 the Roentgen ray shows that the cinnabar goes almost to the foot, and the dissection demonstrates that it goes a little farther than the Roentgen ray indicates. The roentgenograms reveal the inferior vena cava filled with cinnabar in all the dogs except those killed shortly after operation.

The second series of roentgenograms made after the bismuth injection, which gives the general arterial circulation in both legs and both feet, shows quite clearly that below the thigh the arterial circulation is practically the same in the left leg and foot as in the right leg and foot. The second roentgenogram in Dog 1 was not satisfactory, but showed some bismuth in the arteries of both legs. The other four pictures of the second series were quite good. In Dogs 11 and 12, injected shortly after operation, the Roentgen ray shows that the circulation in the left foot and leg was apparently the same as in the right foot and leg. The collateral circulation here was so ample that the bismuth was carried in full quantities from the abdominal aorta around the point of obstruction to the leg and foot. This being the case in dogs that had just been operated on, it is not surprising to find that the collateral arterial circulation in the dogs that lived nine days or longer was at least equally good.

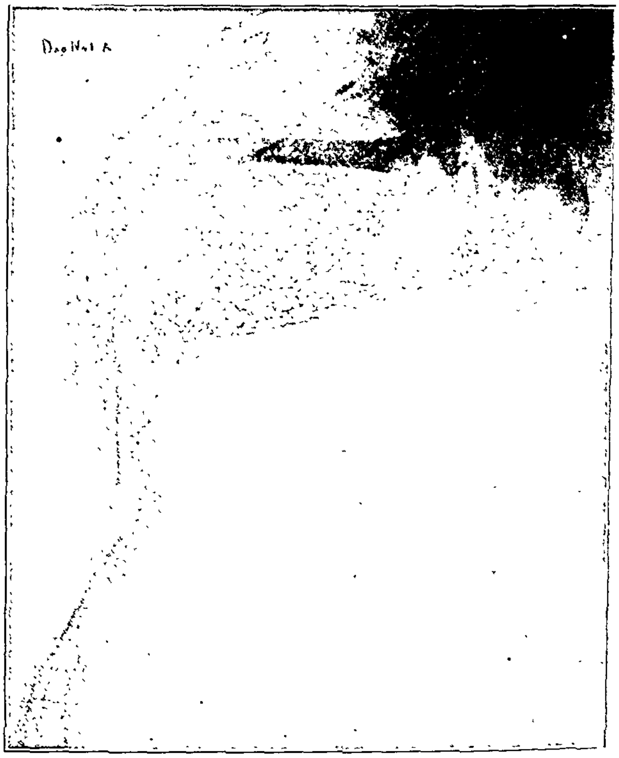

Fig. 5.—Cinnabar mass injected into the reversed circulation of Dog 1, forty-six days after operation. The mass here has reached almost to the foot. Dissection shows that the mass went a little farther than indicated by the roentgenogram. Much of the cinnabar was drained off through the external jugular before it had hardened, so the large veins are not full. The Roentgen-ray plate, however, which is larger than the print, shows the mass in the vena cava.

It seems justifiable to draw the following conclusions from these experiments: 1. The tendency of the arterial blood in a reversed femoral vein is to return to the vena cava by the nearest anastomotic route. 2. In the course of time very large anastomotic veins form so that the mass injected into the reversed circulation quickly and easily finds its way into the vena cava. 3. It is most probable that the arterial blood in the reversed circulation never reaches the ultimate venous capillaries of the foot, but if it does it must be after many weeks, long after the time that any good could be accomplished by bringing nutrition to the tissues, even if nutrition could be absorbed from venous capillaries. These experiments seem to show that even when the full arterial pressure of the femoral artery is turned into the femoral vein by an end-to-end anastomosis, the arterial blood in the reversed vein never reaches the venous capillaries of the foot, and does not even reach the smaller veins in the lower part of the leg for more than twenty-two days.

How, then, can we account for the apparent improvement in many of the reported cases of reversal of the circulation in patients? Certainly not all of these reports can be argued away, and they must rest on some basis of fact. In the successful cases reported, it has been usual to find that the day after the operation the foot appears warmer and the color is better than before operation. It has been asserted, therefore, that the improvement must be accounted for by the operation and by the fact that the arterial blood is reaching the distal parts through the reversed vein. A great many reversals of the circulation have been done by surgeons untrained in blood-vessel surgery who have used the end-to-end method, and it is natural to expect that there will be a large percentage of occlusions by thrombosis following such work. In no other branch of surgery is laboratory experience so essential as in preserving a patent lumen after suturing blood vessels. It is easy enough to unite the artery and vein so that the line of union will not bleed at the conclusion of the operation, but the technically successful operation is the one in which the lumen remains permanently patent. It seems to us that these temporary improvements are best accounted for in the following manner:

The cause of the impending gangrene for which these operations are done is partial occlusion of the artery, while the veins are but little if at all affected. An artery that would normally carry 100 per cent. of its capacity is under these altered conditions carrying only, say, 25 per cent. of its capacity, but the capacity of the veins has been but slightly altered. Now, nutrition for the tissues is taken from the arterial blood in the capillaries and depends not only on quantity and quality of this blood and the ability of the tissues to absorb it, but also to some extent on the length of time during which the arterial blood bathes the tissues. With the artery working normally and the veins normally, a definite physiologic period of time during which the arterial blood remains in the tissues is maintained; but with the capacity of the artery cut down to about one-fourth of normal or even less, and the capacity of the veins but slightly interfered with, the small amount of arterial blood that does reach the tissues is drained away by the unobstructed veins more quickly than normal. The arteriovenous anastomosis stops the venous current in the femoral vein either by the force of the arterial blood stream or, more probably, particularly when done by those inexperienced in vascular surgery, by thrombosis at the site of operation. This, of course, obstructs the vein and more nearly restores the balance between the venous and the arterial circulation. In other words, the operation dams back the arterial blood in the capillaries so that instead of being drained off too rapidly, the arterial blood is compelled to stay the normal time and possibly even somewhat longer than normal. In this manner the improvement as to the color and warmth of the affected limb can be accounted for. But if the occlusion has been by thrombus it will probably extend until too much of the venous system is plugged, and gangrene will follow.

It seems, then, that reversal of the circulation has no legitimate place in clinical surgery, except possibly in Raynaud's disease, if we accept the pathology of this disease as being solely a spasm of the arterioles. In this disease, if a reversal is done as close as possible to the terminal vessels, it might act by so raising the blood pressure in the veins as to cause an intense hyperemia in the capillaries and arterioles; the small vessels may be dilated in the same way as in Bier's hyperemia, only as there would be positive arterial pressure in the veins, the dilatation would be somewhat greater than after a simple Bier's hyperemia. If Raynaud's disease has no organic pathology and is merely a spasm of the arterioles, it is conceivable that this operation might be beneficial, not by sending arterial blood through the reversed veins into the capillaries (for, as shown by these experiments, this in all probability cannot occur), but by maintaining a constant dilatation of the terminal arterioles.

In impending gangrene due to organic disease of the artery of any kind, reversal of the circulation appears unjustifiable. It seems, however, that such cases may be materially benefited by merely ligating the femoral vein. This would tend to balance the circulation by obstructing the venous circulation and permitting the arterial blood in the capillaries to bathe the tissues a longer time than would be the case if the venous circulation was unobstructed. This operation, then, of ligating the femoral vein in threatened gangrene in the lower limb due to partial occlusion of the arteries appears to have a proper field. The resulting improvement should be as great as after any kind of arteriovenous anastomosis, and the operation is much simpler and less dangerous to the patient.

Our thanks are due to Dr. Charles M. Hazen of Richmond, Va., for the Roentgen-ray work in these experiments; to Dr. Arthur S. Brinkley, for assistance in the operations, and to Dr. A. A. Houser for help in injecting the specimens.

Children and Street Work.—Sixteen states and the District of Columbia now have some regulation of street work for children. According to the National Child Labor Committee eight other states are this year considering similar laws. One state with a fixed limit of age for street trading is now proposing to raise the limit. The bills before the state legislatures vary somewhat, but generally they fix an age limit, provide for badges or permits for children at work on the streets, give the school authorities power to grant and recall permits, forbid work at night and empower certain officers to enforce the law. In some states the provision is to be state-wide; in others it will apply to cities of certain size. The tendency is to make the age limit similar to that for child labor in factories. All street trades regulation aims to insure proper schooling for the child. The National Child Labor Committee calls attention to the fact that the most important thing in connection with these laws is to secure their proper enforcement, which is distinctly up to the people.

THE TOOLS OF OUR TRADE

THE INDICATIONS PRESENTED BY MENTAL DISEASE AND THE MEANS AT OUR COMMAND FOR MEETING THEM *

F. X. DERCUM, M.D.
President of the Philadelphia Psychiatric Society; Professor of Nervous and Mental Diseases, Jefferson Medical College
PHILADELPHIA

Under the above caption I propose to review the means at our command for combating insanity after it has occurred. The discussion of prevention is foreign to my present purpose, as is also the general problem of the care of chronic cases. I will therefore leave untouched such questions as those of general hygiene, employment, retraining, after care, family life and like matters, and will turn my attention directly to the purely medical aspects of treatment.

In order that we should realize and view in their proper proportions the indications, possibilities and limitations of the therapeutic means at our command, we must first, though necessarily briefly, consider the nature of the problems confronting us. In other words, previous to an intelligent attempt at treatment, we must have some knowledge, or at least some idea, of the pathology of the diseased states with which we are dealing.

PATHOLOGY IN MENTAL STATES

Considerations into which I cannot enter here point unmistakably to the essentially toxic nature of insanity. In a recent paper on the pathology of insanity, I pointed out that the facts suggest that we have to do with biochemical processes akin to those of infection and immunity; and I instanced in this connection melancholia, which with its history of gradual invasion, maximum onset of symptoms, gradual subsidence and final recovery, presents a striking similarity to an infection. I cannot pause to cite the numerous facts proving the presence of poisons in insanity; suffice it to say that the evidence deals, on the one hand, with poisons introduced from without, and, on the other hand, with poisons formed within the body; that is, the problems presented are of two kinds, namely, those of exogenous and those of endogenous intoxication.

Again, some poisons exercise but a short tenure; that is, the intoxications which result from them are of short duration. In such instances, the organism successfully resists and disposes of the poisons speedily and promptly. The poisons are successively submitted to the defensive action of the gastro-intestinal juices, the defensive action of the liver and other glands, are variously changed chemically, and finally destroyed or eliminated; but these are not the poisons nor the processes which concern us here. The poisons with which we deal in mental diseases are those of long tenure, those which are not destroyed by the various glands and other defensive structures, and which consequently influence the metabolism of the organism for long periods of time, usually many months. Not only is this true of the poisons present in mental diseases which are essentially neuropathic and hereditary, such as the manic-depressive group and the group of the dementia praecox and paranoia, but also of those in which the poisoning is primarily of extraneous origin. Thus, when prolonged insanities ensue after acute infections, the poisons at work have their origin in a secondary disturbance of function of the liver, of the thyroid, of the kidney, of the adrenals and of other glands and tissues. The fact of such involvement is based on indisputable clinical and pathological evidence. Consequently a disorder of metabolism ensues which constitutes of itself an auto-intoxication, an auto-intoxication secondary to the original infection. The instance of alcoholic confusional insanity offers an even better illustration. Here the symptoms of mental disorder persist for many months—long after the patient has ceased to take alcohol. Clearly it cannot be the alcohol that is keeping up the symptoms; the persistence of the latter must be due to autogenous poisons, poisons which are the result of disturbance of function in various organs induced by the alcohol. This disturbance profoundly affects the substances normally elaborated and thrown into the circulation by the various glands and tissues. It would appear, then, that in all long continued forms of mental disease, no matter whether arising spontaneously from poisons bred within the body, or indirectly as a result of infection or poisoning from without, we have to deal with problems of auto-intoxication.

When we come to consider the nature of this intoxication, the facts at our disposal are extremely interesting. We know that these poisons are not mineral salts and also that they are not leukomains. Thus, there are no facts of chemistry to indicate that either the mineral salts or the leukomains are the toxic factors, and secondly, both of these groups of substances are readily eliminated—readily discharged from the organism—while the toxins of insanity are either eliminated very badly or not at all. Indeed, the position of the toxins of insanity is exactly like the position of the toxins of infection, for example, of typhoid fever. No amount of purging, diuresis, or sweating enables us to get rid of the toxins in typhoid fever. The latter are protein bodies, the injurious character of which nature combats by the process of immunization, a process long and tedious. The parallel between the behavior of infection and the course of mental diseases I have already instanced in the case of melancholia; and, indeed, in the manic-depressive group this parallel appears to be complete. It appears also to be complete in the secondary auto-intoxications resulting from the infections, and equally, though less clearly so, in the secondary auto-intoxications following poisons introduced from without. In all forms of secondary auto-intoxication, it may be safely claimed, the tendency is to a restitution of the normal condition.

In the heboid-paranoid group (dementia praecox and paranoia) the picture and the problems presented are much more complex. However, there is again the same unmistakable evidence of toxicity. There is the early period of depression which has a distinct wave-like course followed by a later period of expansion, also wave-like. Accompanying these phenomena there are those of a progressive deterioration which in the larger number of cases terminates in dementia. Some of the cases of dementia praecox, however, as is well known, pass through the cycle of depression and expansion, but instead of permanently deteriorating, terminate finally in a recovery. This recovery, however, is rarely complete; quite commonly it is approximate only. Usually, indeed, evidences of mental reduction are distinctly present. Cases of supposed recovery pass through a recurrence some years subsequently,

---

* Presidential Address, read at the annual meeting of the Philadelphia Psychiatric Society, Jan. 8, 1915.

terminating in a recovery less pronounced than the first, or perhaps with more marked impairment; or, it may be, that this or a subsequent recurrence terminates in a marked dementia. Paranoia and the definitely marked paranoid states we may dismiss by recalling that in them the element of toxicity is revealed by the prolonged wave-like periods of depression and expansion, periods which usually embrace years in duration, and which, as in dementia praecox, are accompanied by a progressive deterioration.

Evidently the difference between the course and termination of the manic-depressive group and the course and termination of the heboid-paranoid group depends on special factors present in the latter. For the sake of clearness, let us turn our attention, first, to the manic-depressive group. It would appear that here in the beginning of a wave, an antigen makes its appearance, and that this antigen is dominant until the fully developed stage is reached, when, after a time, antibodies become dominant and remain so until the normal condition is restored; in other words, until immunity is established. Unfortunately, in very many cases, the process does not end here, but antibodies continue to be formed until they are present in excess and then they in turn take on the character of antigens and a new cycle opposite in its phase is entered on and persists until immunization is again established. Such a view and no other explains the sequence of depressive and manic phases. As to the origin of the original antigens no definite knowledge at present obtains. That they are endogenous must be frankly admitted; that they are due to a disturbance of the hormones, of the internal secretions, using this term in its widest sense, is extremely probable. Finally, that this disturbance is one which permits of complete and full immunization, and therefore of a complete recovery—a recovery without impairment—is a conclusion in accord with clinical experience.

In the heboid-paranoid group (dementia praecox and paranoia), the problem, as already indicated, is somewhat different. We have again to do with affections that are, as in manic-depressive insanity, innately neuropathic, but they present this additional and important fact, namely, that they occur in organisms fundamentally and morphologically defective. The defects are sometimes gross and evident to a degree; at other times they are matters of legitimate inference. As a rule, it is not until the organism enters on the great transformations involved in the transition from childhood to puberty and adolescence, and in the still further change from adolescence to maturity, that the inherently defective and aberrant character of the organism becomes apparent. If the defects and aberrancies are great, symptoms may make their appearance early and give rise to the insanities of adolescence; if they be more recondite, the appearance of symptoms—i. e., the crass appearance of symptoms—may be delayed until later, then giving rise to the various paranoid states of the adult.

Let us turn our attention primarily to dementia praecox. The organism is in childhood able, perhaps, to meet the various demands of its existence. Its chemistry is as yet comparatively simple and it meets its physiologic necessities in a normal, or in an approximately normal, manner. As puberty is approached and entered upon, however, everything is changed. The sex glands, and with them all of the other glands of internal secretion and hormone producing structures generally, take on a new rôle. A new chemistry is entered on. The organism being badly constructed, this chemistry becomes aberrant and toxic. Some years ago, together with Dr. A. G. Ellis, I pointed out that the ductless glands in dementia praecox differed from normal ductless glands, among other things, more or less markedly in weight, and also, it seemed, in structure. Later, Fauser, by employing the method of Abderhalden, demonstrated the presence of ferments in the blood whose action can only be interpreted as a defense against the sex glands, and, in given instances, also against the thyroid and the cerebral cortex. Fauser's findings have been confirmed, with some variation of detail by a large number of other investigators, and the inference that in dementia praecox there is a profound disorder of the internal secretions involving the sex glands, the thyroid and in all probability other structures, is unavoidable. The studies of the rôle of the sex glands in dementia praecox by Parhon and his associates likewise admit of no other conclusion, and this is also true as to the involvement of the thyroid gland. It may now be stated without fear of contradiction that the theory of a disturbance—an imbalance and other change—of the internal secretions in dementia praecox has left the realm of speculation and has entered on that of established fact. In other words, as in manic-depressive insanity, the organism in dementia praecox is autotoxic, but this autotoxicity stands in a very different relation to immunity than it does in the manic-depressive group. The clinical history of dementia praecox, the fact that it presents a wave-like initial period of depression followed later by a wave-like period of expansion, suggests, of course, the interaction of antigens and antibodies similar to that which is indicated in manic-depressive insanity. As in the latter, the patient may pass through an attack of dementia praecox without presenting at the end any mental impairment; but this is, as I have already pointed out, distinctly the exception. The course of the affection in by far the larger number of cases is attended by a mental impairment that is progressive and finally pronounced; and yet we must recognize in its wave-like course—often clearly marked in the remissions and recoveries which every now and then ensue—the effort of the organism to overcome toxicity, to restore the balance of nutrition, to bring about immunization. That this immunization is difficult and often incomplete results probably from the inherently defective make-up of the organism. It would also appear that the antibodies, that is, the ferments which arise to defend the organism against the perverted and therefore toxic internal secretion of the sex glands, have unfortunately also a fermentative, a destructive action on the cerebral cortex. The disorder and imbalance of the internal secretions are thus clearly shown; first, in that the internal secretion of the sex glands acts as a foreign body and assumes the rôle of an antigen, and secondly, in that the antibody evolved has a toxic action on the brain and other structures. The point of practical importance for us, however, is that, in spite of her frequent failures, nature makes an effort—often a prolonged effort—to combat the auto-intoxication of the patient and to bring about immunization.

TREATMENT

With these preliminary considerations of the pathologic processes going on in our patients, let us turn our attention in the treatment or management of these disorders; first, to the indications present, and secondly, to the means at our command. The first indication is evidently to assist, if possible, in the production of antibodies. In the cycles of melancholia and mania, and in the secondary auto-intoxications of ectotoxic patients, the indications are very clear and the outlook most promising. What can we do here to assist nature? In what way can we favor the production of immune bodies? Evidently the resources of the organism are increased by adding to its substance, and the first indication is to give an abundance of nourishment, to practice full feeding just as we do in tuberculosis and in states of depressed nutrition generally. Full feeding does more than to add to the weight of the body and to encourage the repair of exhausted tissues; it distinctly favors the formation of lipoid substances, substances which we now know play a most important rôle both as antigens and antibodies. The rôle and significance of lipoids is well shown by an instance such as the following: A patient with a clear history of syphilis was submitted to the Wassermann test of the blood, but with a negative result. On further examination it was found that the patient was a little obese, a little overweight; in short, in a condition of hypernutrition. He was then placed for a time on an exclusive and limited diet of skimmed milk, together with the daily administration of salines. The blood being again examined after an interval of ten days or two weeks, the Wassermann reaction now proved to be positive. It was negative at first, probably because of an excess of lipoids.

The practical results of full feeding, and at times of massive feeding, are so well known as not to call for comment. That these results are due not only to a general improvement in nutrition, but also to the more liberal and readier formation of antibodies, is a most important fact for us to recognize.

The thought arises whether it would not be of value to administer lipoids—for instance, cholesterin or lecithin—to our patients directly to hasten, if possible, the production of immunity. It is probable, however, that lipoids introduced by the intestinal tract would be in some way changed either by the process of digestion or in their passage through the liver so as to lose their specific value. A parenteral introduction would therefore be indicated; but whether such an introduction could be successfully accomplished and, especially, in sufficient amount to have an appreciable effect, would be a matter for experiment.

An expedient practiced more especially by Pilcz in Vienna here deserves mention. It is a well known fact that an infectious process, such as erysipelas, sometimes leads in paresis to a remission. This is in keeping with the fact that an attack of typhoid fever or other acute infection occurring in the course of a melancholia, mania or it may be of some other psychosis, frequently leads to an abrupt termination, a cure, of the attack of insanity. Evidently this result is due to the fact that the infection stimulates the formation of antibodies. Pilcz, taking advantage of this fact, has inoculated cases of paresis with the toxins of erysipelas and has thus induced remissions.

The second indication of therapeutics in mental disease, one which is naturally and closely associated with hypernutrition, is rest. Rest, whether it be relative, partial or complete, is an indication as clear as that of full feeding. Indeed, rest is a veritable prerequisite of hypernutrition. Unfortunately it is rarely carried out in this country as radically as it is in Germany. Rest in bed is with us, as a rule, limited to the few patients who cannot get out of bed and is not applied as a special procedure to any large proportion of cases. Neurologists apply rest to their cases of neurasthenia, hysteria and allied functional affections and to the rather limited number of mental cases suitable for extramural care. That by this means recovery is greatly hastened, is a matter of such general experience as to be beyond question. It is rather remarkable that the Weir Mitchell method has been so little applied in the asylums of this country, while it has been applied, in principle at least, most extensively in Germany. Hypernutrition is in many cases impossible without it. We rest and full feed our cases of infectious diseases, for example, tuberculosis; why should we not rest and full feed the autotoxic, the—so-to-speak—self-infected patients whom we term the insane?

Thus far we have become acquainted with two tools of our trade, full feeding and rest. Full feeding has been long appreciated and understood by us, but this cannot be said of rest, that is, of radical rest in bed extending over months of time. That its value is inestimable Weir Mitchell long ago demonstrated and every neurologist can confirm. Its introduction into our asylums on a true hospital basis, with adequately trained nurses, is to be, I believe, one of the great achievements of the future.

We must now pause to turn our attention to a special and extremely important point both of etiology and therapeutics. Since the introduction of serologic studies, the Wassermann reaction has been found to be positive in a very large number of the insane. Not only has it been found to be positive in 100 per cent. of paretics, but also in a large proportion of defectives; not only in feebleminded and idiotic children, but notably also in cases of dementia praecox. In my personal experience, the Wassermann reaction has proved positive in dementia praecox with suggestive frequency, but attention should be especially directed to statistical studies such as have recently been published by Max A. Bahr in the Report of the Pathological Department of the Central Indiana Hospital for the Insane. Bahr found that the Wassermann reaction was present in 32.1 per cent. of his dementia praecox cases. Certainly such a finding cannot be a coincidence, but must have a profound significance. The importance of the result grows when we recall that in paresis and tabes the earlier writers claimed that only a percentage was due to syphilis while it is now admitted that *all* such cases are syphilitic in origin. It is probable that an improvement in methods will gradually add to the number of dementia praecox cases in which syphilis can be demonstrated. It is well known that children in whom the clinical evidences of inherited syphilis are indubitably present frequently yield a negative Wassermann. Probably this is due to the presence of an excess of lipoid substances; possibly to other and as yet unknown factors. At any rate, we should at present recognize that the study of a case of dementia praecox is not complete without a Wassermann examination, at least of the blood. If the latter fails, a luetin test should be made or possibly the sero-enzyme test according to the method of Abderhalden, as has recently been quite extensively done by Baeslack. Possibly these and other methods still to be devised, will prove that all cases of dementia praecox bear the evidences of a syphilitic inheritance. It is also a suggestive fact that cases of dementia praecox are—at least in my experience—

remarkably tolerant to mercurials. However this may be, the question that immediately concerns us is, Are the symptoms of dementia praecox to be regarded as the result of an active syphilitic process or are they to be regarded as due to the breaking down of an organism whose glandular and general organic evolution has become defective and aberrant, due to the presence, during the period of development, of the treponeme and its toxins? I fear that an increasing knowledge will reveal the latter to be the correct interpretation, and that antisyphilitic remedies will in dementia praecox accomplish but little.

The question further suggests itself, Do other infections have a similar effect on the embryo, the fetus, the developing child? While this is not impossible, little can be directly laid to the door of the acute febrile infections, the exanthemata, judging from our clinical histories. How is it in regard to tuberculosis? We can safely answer that the facts as to a tuberculous ancestry in cases of dementia praecox are inconclusive. Patients with dementia praecox, it is true, often betray an undoubted tendency to tuberculosis, a true anaphylaxis, but it is extremely probable that this anaphylaxis is not hereditary, but exists as a direct result of the imperfectly developed, the damaged, glands of internal secretion. This is doubtless the real reason for the lessened resistance to tuberculosis. On the other hand, tuberculosis in the ancestry does not seem to be a cause of dementia praecox.

It can hardly be doubted that the remarkable relation between syphilis and dementia praecox which is now coming to light and which seems to be becoming more clearly defined with increasing experience, will greatly influence our therapeutics. It would seem that in a given case we are not discharging our full duty unless specific treatment be not only instituted, but pushed until the Wassermann reaction becomes negative. Again, the question arises whether examinations should not be made of the cerebrospinal fluid and treatment with intraspinous injections of salvarsanized serum carried out as in the treatment of tabes and paresis. Certainly here are matters which merit our most thoughtful consideration.

TREATMENT OF SPECIAL SYMPTOMS

Having considered various factors, general in their character, both of pathology and therapeutics, let us now turn our attention to the various measures at our command for the control of special symptoms. Among these is the bath, more especially the continued warm bath first used in Germany. That this continued warm bath is wonderfully efficacious in disturbed and excited cases is of course well known. It is a procedure especially adapted to active deliriums, to acute mania, to the excited periods of dementia praecox and to other active disturbances. As a rule, the patient who has been struggling soon becomes quieted by the procedure, and the effect persists for some hours or longer, after the patient has been taken from the bath. The question arises, How is this effect produced? The bath undoubtedly stimulates elimination by the skin, and it is not improbable that in disturbances normally of short duration, for example, alcoholic and other deliriums, the stimulation of the cutaneous elimination is the important factor at work. However, this is evidently not the case in other and long continued disturbances, for example, in true mania. No procedure as yet devised will cut short or abort an attack of mania; while the continued bath lessens the disturbance, it does not in any way lessen the duration of the manic wave. Similarly no method of bathing can lessen the duration of an attack of melancholia; melancholia for some reason when accompanied by disturbance, as in the agitated form, does not yield, as do other excited states, to the bath; indeed, the continued bath is not applicable to this affection. Further, as regards dementia praecox, while the bath lessens the excitement in disturbed cases, it cannot in any way influence the latter in duration. Finally, elimination cannot be the active factor in the quieting of mania and of the excited periods of dementia praecox, because the toxins present *cannot* be eliminated by the skin, no more—as has already been pointed out—than can the toxins of typhoid fever. As in typhoid fever, nature appears to combat the toxins of insanity by the slow and tedious process of immunization. In what manner, then, does the bath quiet the disturbed patients? It would appear that the warm water of itself has a calmative effect, a relaxing influence. In addition, the fact that the clothing has been removed and that the body half-floats in the water, lessens the tendency to resistance. Resistance is to a large extent reflex and is stimulated by that which it encounters. Possibly a contributing cause is also the fall of blood pressure in the peripheral vessels. However, this may be, the continued warm bath is also a form of restraint, and as such is the best, the most humane, the most physiologic form of restraint yet devised. Similar remarks are applicable to the warm pack. Here the warmth and the free sweating induced are likewise factors conducing to the relaxation and the calming of the patient, but the pack is in addition also a method of restraint. The word restraint has very unpleasant associations and another word such as "control" would be very much better. Years ago Dr. John B. Chapin suggested the word "disturbed" as more suitable and less offensive than such expressions as noisy, maniacal or excited when applied either to patients or to the wards of a hospital. The introduction of the word "disturbed" constituted a distinct advance in our terminology, and in the same way such a word as "control" would be much more acceptable than the old word restraint, and especially so as restraint in the old sense has practically disappeared from our asylums.

Other methods of hydrotherapy than the bath do not in the present paper call for consideration. There is one procedure, however, which deserves especial mention and which I believe in given instances to be of great value. I refer to the employment of hypodermoclysis in certain stuporous cases, as is practiced abroad, more especially by Pilcz of Vienna. Hypodermoclysis is obviously inapplicable to the stupor of catatonia or the stupor of melancholia; it is, however, undoubtedly applicable to the stupor of infection and exhaustion. Here it unquestionably stimulates elimination. I have on a number of occasions had the opportunity of employing this method in such cases with very satisfactory results. The procedure is unattended by risk and should, I believe, be more frequently practiced than it is. It has been carried out by Pilcz for years with marked success.

Another special indication in the treatment of mental cases is the production of sleep. There can be no doubt that this is one of the most important indications presented, and one that is often very imperfectly and half-heartedly met. Simple physiologic methods of inducing sleep, such as exercise, bathing, massage, the drip sheet, the taking of food, of hot milk, suggestion, placebos, may all fail and indeed do fail in a large number of cases. If the patient secures some sleep, say four or five hours out of the twenty-four, we may be justified, other things equal, in withholding sedatives. If, however, the insomnia is very pronounced and persistent, grave danger both to the physical and the mental condition of the patient may ensue. The mental symptoms may become more pronounced and grave exhaustion may supervene. Indeed, patients have been known to die from the want of sleep and the accompanying exhaustion. Further, a long experience with the milder forms of mental disease such as are treated outside of institutions, as well as with the early periods of the more pronounced forms, has convinced me that the prompt correction of sleep disturbances is of the utmost importance. Many patients in whom this matter is neglected become rapidly and markedly worse. Others, again, in whom it receives prompt attention, are often spared a prolonged or a grave attack. As we have just seen, physiologic methods often fail to induce sleep; what then are we to do, especially when the patient's need is urgent?

Of late years a prejudice has grown up in the mind of physicians as to the use of sedatives. This prejudice is often so strong, especially in institutions, as to lead to an utterly inadequate use of these remedies or even to their entire exclusion. This prejudice, I am convinced, has its origin in the following causes: First, it is a reaction against a former somewhat too free use of these remedies; secondly, it has its origin in an insufficient and often mistaken knowledge of their mode of action, and in an exaggerated fear of their harmful effects; thirdly, the prejudice has been distinctly fostered by the attitude of the lay public, and especially the lay press. The word "dope," a slang word of the slums, has in large degree replaced such words as "medicine" and "remedy." The word "dope" is not only used by the laity and the lay press, but, I am sorry to add, even by some physicians. The latter have, in a degree, encouraged an unscientific attitude toward sedatives that has worked injury to their patients. Drug habits cannot and do not ensue if the physician exercises a reasonable precaution. This may in private practice entail some difficulty, not, however, in institutions, for here the administration of the remedy given is completely under the control of the physician. Physicians in private practice are, in my observation, habitually exceedingly careful in prescribing sedatives. Many physicians do not prescribe them at all unless the medicine is to be given by a nurse to whose hands the control of the remedy is thus confided. Whatever may be said as to these details, however, there cannot be any doubt as to the necessity or propriety of their use under given conditions. To withhold them under given conditions is equivalent to withholding nitrous oxid during the extraction of a tooth or denying a patient the sleep of ether during a surgical operation. Further, just as skill and judgment are required in the giving of an anesthetic, so are skill and judgment required in the administration of sedatives.

Time will not permit us to consider more than a few general principles. An ideal remedy would be one which would induce a sleep approximating the normal sleep and which would be followed neither by physical depression or other unpleasant symptoms. A large number of sedatives are at present at our disposal and many of them fulfil, approximately at least, the above conditions. Recently Dr. Richard Eager[1] of the Devon County Asylum, at Exminster, England, has carefully reviewed the use of sedatives. He points out the necessity of procuring sleep in certain cases, and that physiologic methods often fail completely. He points out especially the necessity of procuring sleep in cases with depression that threaten to be cases of melancholia, and further, that many of the hypnotics that are used induce sleep which is like the natural sleep and are not attended by depression or unphysiologic effects, and he insists that patients every now and then die from the exhaustion which the want of sleep induces. Some medicines are comparatively harmless; others have cumulative effects. Some do not conduce to the formation of drug habits; others still are liable to do so, especially if prescribed recklessly.

Of course all physicians recognize that sedatives should not, save exceptionally, be used over long periods of time. Their obvious application is to secure the immediate relief of a distressing insomnia. Frequently after such relief has been secured the patient continues sleeping without the medicine, or under the influence of a placebo. In given cases, should this not be the result, the remedy should, notwithstanding, be from time to time suspended, and, if later a sedative again becomes necessary, an entirely different one should be given.

Insomnia as met with both in the neurasthenic states and in the course of the various mental diseases, is unquestionably toxic in its origin and is but one of the many symptoms expressive of the toxicity from which the patient suffers. Compared with this toxicity the action of sedatives is evanescent. Their effect on the nervous tissue is merely transient and no harm can come from their judicious application; indeed, incalculable benefit often follows their use.

Further, another and most important point remains to be considered. When drugs are used habitually, tolerance to their use, as we all know, is sooner or later established and an increasing dose is required to produce an effect. The establishment of this tolerance doubtless depends on the formation of antibodies; in the case of some drugs, for example, morphin, the formation of an antitoxin has been definitely proved.[2] This fact has, however, an added significance. Justschenko and other writers point out that under the use of sedatives, lipoid substances are increased in amount. Justschenko declares that biochemical investigations have shown that under the influence of sedatives, for example, in severe melancholias, there is an increase of cholesterin in the blood, and cholesterin is, as is well known, a powerful antitoxic and antihemolytic body. In other words, sedatives directly stimulate the formation of antibodies, and there can be no doubt that in their judicious use we have, in given instances, a valuable means of aiding in the recovery of our patients.

I will not discuss the detailed properties of the various drugs nor their detailed application; this time forbids. The facts can be obtained in any text-book such as that of Kraepelin or in such admirable articles as that of Eager[1] already referred to. A few general statements, however, may not be amiss. Personally I never use—or very rarely—the alcohol group of sedatives, which includes, among other things, alcohol, paraldehyd, amylene hydrate, chloral hydrate, and

1. Eager, Richard: Jour. Mental Sc., July, 1914, p. 461.
2. Hirschlaff: Riedel's Berichte, 1904, p. 27, also Abstr., Jahresb. f. Neurol. u. Psychiat., 1904, p. 1228.

butyl chloral hydrate. Alcohol is sometimes given to promote sleep in persons suffering from neurasthenia; more especially in the form of beer or ale. The sleep so induced, however, is not apt to be prolonged, and besides the wisdom of prescribing alcoholic beverages for neurasthenics may well be questioned, and I have rarely so employed them. In the therapeutics of fully developed mental disease alcohol plays no rôle whatever. Of the other sedatives belonging to the alcohol group, all may be dismissed as no longer necessary since they have of recent years been displaced by other and more serviceable remedies. Perhaps an exception should be made in favor of paraldehyd. The latter has the great advantage of acting with the utmost promptness and certainty and at the same time of acting as a stimulant and not as a depressant. Its unpleasant odor and taste, however, make it difficult of administration save in alcoholic subjects, who take it very readily when it is suspended in whisky. It is therefore especially adapted to procuring a first sleep in alcoholic delirium and, because the sleep induced is short, some other and more slowly acting remedy may be given at the same time.

The sulphonal group presents several valuable sedatives; each of which has special advantages. Trional acts kindly and without depression or subsequent unpleasant after effects. Sulphonal acts slowly and is of special advantage when it is desired to procure a prolonged sleep. Like trional, its action is not accompanied by depression, but because it is slowly eliminated some hebetude may persist for some time after awakening following full doses. Tetronal closely resembles trional. Porphyruria, said to follow the too free administration of the sulphonal group, I have not met with.

The group of veronal, medinal, luminal and adalin appear to be especially valuable. Veronal in too free dose gives rise to a sleep that is too prolonged and is in some instances followed by heaviness and hebetude. Medinal (veronal sodium) is eliminated with great readiness; it acts very promptly, the sleep approximates the normal, there is no depression and no unpleasant after effect. Luminal, which is much lauded by Eager, I have little personal experience with, but it seems to be worthy of trial. Adalin appears to be an almost perfect hypnotic. The sleep induced is light and gentle and unattended by any concomitant or subsequent effects. It has the further advantage of being efficacious in relatively small dose, e. g., 5 grains; although not infrequently 15 grains are required.

The bromid group can be dismissed with the statement that they are not suitable for prolonged periods of time, and not as valuable, as hypnotics, as other remedies in our possession. Opium and its alkaloids also appear to have a very restricted application. Opium, however, is especially recommended by Eager in agitated melancholia. No drug habit follows its use in such cases, even when the administration is prolonged. Scopolamin is a drug of undoubted value. It is efficacious in producing quiet and sleep in even so small a dose as 1/400 grain, though commonly 1/200 or 1/100 of a grain are required. It has of late attracted renewed attention through its use in the production of the so-called "twilight sleep" in the obstetric clinic at Freiburg. Administered hypodermically together with morphin (1/100 of a grain of scopolamin and ⅛ of a grain of morphin) rapid sedation and sleep follow. The sleep is not profound, but the patient can be handled and submitted to various procedures without the slightest difficulty. Genito-urinary surgeons have time and again had recourse to this method in operations on the prostate gland in cases in which ether or chloroform are inadmissible. Some German physicians give a struggling patient a hypodermic injection of scopolamin and morphin previous to placing him in the continuous warm bath. This method seems to be better than Kraepelin's plan of giving such patients a 30 grain dose of sulphonal. No depression and no unpleasant after effects follow the administration of the combination of scopolamin and morphin. It is remarkable also that the effect produced by small doses is far greater than when either drug is used alone in full dose. If scopolamin be used alone in large dose, it may be followed by dryness of the mucous membranes. Hallucinations and even delirium are also said to follow its too free use. This, I am convinced, is rare. Finally, it should be added that such a thing as a scopolamin habit is unknown.

Other modes of treatment than those considered in this address do not differ from those applicable to internal medicine and need not detain us here. Further, glandular extracts, which now play a limited rôle, may possibly play a more extensive rôle in the future. It is to be hoped, too, that the science of serology will in due course yield us antitoxins and perhaps also other remedies of the nature of salvarsan, a consideration of which I cannot in this essay even touch on. I have merely attempted to outline the facts, the wonderful possibilities and the great promise of the future.

THE EMPLOYMENT OF BORIC ACID IN DISEASES OF THE SKIN

DOUGLASS W. MONTGOMERY, M.D.
SAN FRANCISCO

Boric acid has a very extensive use in diseases of the skin, but it is almost always employed as an adjuvant. This subsidiary position, however, does not detract from its importance, but rather adds to it, as by its correct application in a multiplicity of ways the efficacy of the main therapeutic agent is often heightened. As, however, it is a subsidiary remedial agent, treatises on therapeutics and on skin diseases give it far less notice than its real usefulness demands.

Boric acid is a mild, non-irritating antiseptic. In fact, it is not only non-irritating; it is soothing and is used as a soothing lotion in the eye. In conformity with its real nature the powder feels smooth and unctuous. As in many instances an afflicted skin is irritated not only from an infection but also from the state of the system, the advantage of employing an antiseptic that is at the same time bland and soothing, is obvious, even if the antiseptic action is weak or only inhibitory.

Pure water, by increasing osmosis from the papillary layer of the skin, may act detrimentally, especially in superficial inflammations. When, however, boric acid is added to water it, like common salt, increases its tonicity and prevents this detrimental action. In this way a bland, soothing solution of approximately normal tension is secured, the action of which is especially beneficial when the skin is denuded of its horny epithelial covering and the papillary layer is exposed, as in catarrhal inflammations, such as eczema, or superficial dermatitis, as "poison oak." In such cases if a moist dressing is for some reason desired, a solution of boric acid often answers admirably.

ACNE

An initiatory soaking with a hot boric acid solution is often of great benefit in the local treatment of acne. For this purpose it is desirable to apply the solution hot and to use a large quantity of it, so that the heat will be retained for a considerable time. Three heaping tablespoonfuls of boric acid powder are added to the usual quantity of water used in washing—about 3 quarts. This makes approximately a 3 per cent. solution. The patient should then sit, leaning over the bowl, and soak the face well with towels wrung out of the hot solution. As the solution grows cooler, more hot water may be added. It is often advantageous so to soak the face for ten or fifteen minutes. It softens the epithelium and acts as an excellent detergent, removing the grease and many of the micro-organisms, and decidedly increases the efficiency of a resorcin or sulphur application.

PYOGENIC INFECTION OF THE SKIN

Pyogenic infection of the skin is a convenient term to employ for a number of different affections mostly caused by either staphylococci or streptococci. In many of these the susceptibility of the individual plays an important, even a dominant part, and the constitutional condition must be met by measures appertaining to diet and general medicine. Topically, boric acid and its preparations are of great value, but frequently, as before mentioned, in a subsidiary or adjuvant sense.

FURUNCLE

Moist heat together with a non-irritating antiseptic are the topical therapeutic indications in the primary stage of active congestion in furuncles. These indications may be met by employing gauze dipped in hot saturated (4 per cent.) solution of boric acid, and enveloping with oil silk to retain the moisture and the heat. This is similar to a poultice, but is not so good, as it is not so bland and does not retain the heat so well; it, however, is often sufficient, and is easier to apply. An admirable poultice for this purpose is made by mixing boric acid powder with starch paste. The preparation of this will be taken up later.

There are some special kinds of furuncles that deserve more detailed mention.

Furuncle of the edge of the eyelid, hordeolum or stye, is one of the most exasperating, painful, and it may be one of the most persistent of troubles. It begins as a little red point on the ciliary border, and in about three days a white center shows in the red swelling. It opens, a little core is expelled, and healing takes place. In about a week, at another part of the edge of the lid, another red point appears that goes through the same stages. At times, instead of styes coming singly, a number appear bordering both lids, and then the affection is most distressing indeed. Long ago Hardaway[1] pointed out that styes may be due to infection from the scalp, and that when seborrhea capitis is present it should also be treated. Furthermore, many of the patients, suffering from styes, have blepharitis ciliaris, which is frequently an expression of the same seborrheic habit.

In the treatment of styes I have usually come out fortunately by ordering persistent bathing and soaking for half an hour twice a day with warm saturated solution of boric acid, and after each soaking to rub in a salve of 1 per cent. red mercuric oxid in vaselin.

Suppurative folliculitis of the vibrissae of the nares is another pyogenic affection in which boric acid may be employed with advantage. This folliculitis is a most tantalizing affection, and is often combined with cracking of the mucous membrane at the anterior angle of the nares, constituting one of the causes of red nose. These lesions may also plague in another way, by furnishing a convenient entrance for the streptococci of erysipelas. An efficient manner of treating this folliculitis is to set before the patient a tin cup of saturated solution of boric acid, kept hot by placing it over the flame of a spirit lamp. The patient takes pledgets of absorbent cotton, dips them in the hot solution, and pushes them into the affected nostril, repeating this during ten or fifteen minutes till the tissues are well softened, and the crusts softened and loosened. Calomel, 12 per cent., or xeroform, 12 per cent. in vaselin, is then well rubbed in. This procedure may be repeated two or three times a day. Care must be taken both to soak thoroughly and anoint the fossae behind the nose tip, as these hollows are a favorite residence for germs in this affection. Epilation may or may not be necessary.

IMPETIGO CONTAGIOSA

Streptococcic infection of the skin when it appears as impetigo contagiosa frequently justifies its name of the impetuous disease, or the quick striker. Like all the streptococci, those that cause impetigo contagiosa love fluid, which they cause to pour out as serum from the papillary blood vessels. This sticky serum forms heavy crusts that constitute an excellent protection for the underlying anaerobic bacteria. One of the chief therapeutic indications is to remove these crusts without doing any damage to the inflamed skin. This may often be best accomplished by applying a boric acid starch poultice. The making of this poultice is a simple matter, but it is often the simple matters that are the most neglected. It is made in the following manner:

Take ordinary, common, lump, laundry starch and pulverize it. This pulverization is to be done before measuring. Dissolve one slightly heaping tablespoonful of the pulverized starch in two tablespoonfuls of cold water. Add to this one coffee cupful of boiling water, stirring rapidly until the mixture is a thick paste. To this paste add a tablespoonful of boric acid, free from lumps, and stir well until thoroughly mixed. Fold the warm jelly between layers of thin muslin or cheesecloth, and apply as hot as can be borne.

A good poultice should not be too thin or it will dry, nor too bulky, or it will run; it should be slightly less than a finger thick. In order to prevent the borders drying and sticking to the surface, they may be greased with vaselin, oil or zinc oxid ointment.

This poultice is not gummy like a linseed poultice, is cleaner looking and retains heat just as well. Besides the foregoing use, such a poultice has a multitude of applications, sometimes being employed hot, sometimes cold, as pointed out by Sabouraud. Sabouraud rightly objects to the disrepute into which, of late years, poultices have fallen, and rightly asserts that many of the objections emanate from men who slavishly follow a popular cry.[2] It is true that antiseptics, among those who are imperfectly grounded in bacteriology, assume many fantastic and doctrinal forms, and that there is no scoffer nearly so sneering as the one with imperfect knowledge.

---

[1] Hardaway and Grindon: Cutaneous Therapeutics, Philadelphia, Lea and Febiger, 1907, p. 38.

When, by means of this poultice, the crusts are softened and loosened, they may be gently removed. This removal is often best accomplished by rubbing in a salve containing an appropriate antiseptic, such as ammoniated mercury. The following ointment is an excellent one for the purpose:

	gm.	
℞ Ung. hydrargyri ammoniati..	15	℥ ½
Ung. zinci oxidi............	30	℥ i

M. Use twice a day both to clean and dress the affected surface.

The real efficient antiseptic in the above is the ammoniated mercury, a remedy familiar to every skin clinic in which naturally streptococcic infections are among the daily visitors. The 10 per cent. ointment of the Pharmacopeia, however, is too stimulating, and the zinc oxid ointment both dilutes it and modifies its asperity.

As a general lotion for more widespread use in very scattered pyogenic infection of the skin, a saturated solution of boric acid in dilute alcohol serves admirably. It is harmless, it is clean and does not stain, and is not disagreeable in either appearance or odor, and because of the alcohol cutting the fat of the cutaneous surface, both the alcohol and the boric acid are permitted to act effectively as antiseptics.

PERLECHE

Perleche is another streptococcic infection, with a name that should be a delight to a philologist, as it is so closely connected with the etiology of the disease. It is derived from the French *lecher,* to lick; in fact, our word lick, the German *lecken,* is the French *lecher,* therefore it really is the lick disease. It is an infection in the corners of the mouth in infants. They constantly lick it and therefore keep it moist and in a favorable condition for the further growth and residence of these moisture loving micro-organisms. The affection may spread down on the outer surface of the lip and supramental fossa, where the little pink washrag of a tongue follows and entertains it. The persistent foci, however, remain in the corners of the mouth, where there is cracking and a characteristic grey veil-like covering. Pledgets of cotton wet in warm boric acid solution should first be industriously sopped into the corners of the mouth, and, if possible, drawn across the corners saddlewise and left there. After this is thoroughly done, the ointment composed of the ointments of ammoniated mercury and zinc oxid, previously recommended, is rubbed in.

PARONYCHIA

Another pyogenic infection due, in at any rate the majority of instances, primarily to streptococcic infection followed by staphylococcic fouling, is the painful affection in the neighborhood of the nails called runaround, paronychia or felon. When the affection has gone to the length of suppuration, it must be lanced, but before this occurs the process may be aborted by appropriate treatment. Both as an abortive measure, and as an antiphlogistic antiseptic measure, a dressing of a combination of boric acid and liquor alumini acetici may do excellent service. A lotion is made of:

	gm. or c.c.	
℞ Liq. alumini acetici.........	30	℥ i
Acid boric sol. sat.........	300	fl℥ x

M. Employ warm to bathe the finger, and also as a wet dressing.

Gauze soaked in this solution is wrapped about the finger, and then an amply fitting rubber finger-stall is drawn over it and retained by a not too tight bandage.

Liquor alumini acetici is among the best of the mild antiseptics, and is gradually coming into favor in surgical clinics.[3] It must be carefully prepared, and should be diluted about ten times. The water employed in its dilution is not an indifferent matter, as that containing carbonates throws down a heavy gelatinous precipitate of aluminum hydroxid. As the foregoing prescription is put up by a druggist, and with distilled water, this mischance is avoided.

ULCUS CRURIS

Ulcus cruris is almost always a streptococcic infection on a leg in which the resistance is lowered by circulatory disturbances due to varicose veins. These circulatory disturbances not alone lower the resistance, but they increase the susceptibility to streptococcic attack by increasing the amount of fluid in the tissue. As has been before mentioned, the streptococcus is an ardent lover of fluids. These are not the only causative factors in ulcus cruris, which has a most complicated etiology, but the mention of the edematous condition of the tissues and the presence of streptococcic infection serve to elucidate why these ulcers are so irritable, so watery, so heavily crusted, and why they have, when neglected, such a bad, penetrating odor. The irritable condition of the tissues precludes the employment of all strong antiseptics. Nothing will clear off the crusts, deodorize the lesions and inhibit the infection so well as a boric acid starch poultice. This naturally does not constitute the alpha and omega of treatment in this complicated and highly interesting disease condition, but it does form a most welcome help in some of its incident conditions.

Used either alone or combined with other powders, boric acid is very valuable in many discharging diseases of the skin. An excellent powder is made of equal parts of boric acid and talc, or of equal parts of starch, zinc oxid and boric acid.

The boric acid ointment of the Pharmacopeia contains about 8 per cent. of boric acid, while Lister's ointment is much stronger—about 16 per cent. Boric acid ointment is an excellent non-irritating preparation with a multitude of uses. It is an ointment that, more generally than any other, is well prepared, and this is a point of importance when the druggist who is to put up a prescription is not known, as ointments are often wretchedly made. In seborrheic conditions this ointment will sometimes agree when those more usually employed fail.

The presence of boric acid in a great number of proprietary remedies and pharmacopeial compounds is also a proof of its usefulness as a topical application.

It is well, occasionally, to review what help we may receive from the humbler members of our Pharmacopeia, as they sometimes may aid us when the more dramatic ones fail. The practice of medicine is the study of life, and life is composed of little things, and these little things we cannot despise. It was a favorite saying with the late Professor von Leyden: "For the patient there are no small things."

---

[2] Sabouraud, R.: Le Cataplasme de fecule en dermatologie, Les Entretiens Dermatologiques, 1913, p. 415.

[3] Meyer and Gottlieb, in their admirable book on therapeutics, Die experimentelle Pharmakologie, Berlin, 1911, p. 464, mention aluminium acetate (liquor alumini acetici, essigsaure Tonerde), saying that it stands on the borderline between astringents and antiseptics, and that it is coming more into use as a mild antiseptic in wounds.

323 Geary Street.

THE SIGNIFICANCE OF TUBERCLE BACILLI IN THE URINE*

LAWRASON BROWN, M.D.
SARANAC LAKE, N. Y.

The significance of tubercle bacilli in the urine may or may not be grave. I shall consider it first, from the point of view of discovery of tubercle bacilli in the routine examination of the urine of tuberculous patients; and, secondly, from that of finding tubercle bacilli in the urine of a patient with symptoms, more or less pronounced, referable to the urogenital tract.

ACID-FAST BACILLI

Before discussing these points, however, I would like to say a word about the acid-fast organisms and their differentiation from tubercle bacilli.

The cold blooded tubercle bacilli, while possibly slightly infectious for man, and while it is possible that they might be excreted through the kidneys when injected into the body or circulation in large quantities, can in most patients be disregarded. Lepra bacilli and acid-fast streptothrices (actinomycosis) play here a small part also. The milk and butter bacilli and the timothy hay bacilli may possibly be excreted through the urine, for the work of Calmette and Ravenel has shown that in dogs tubercle bacilli in a fatty emulsion are readily absorbed from the intestine and pass through the thoracic duct into the blood. These organisms, therefore, must be borne in mind, but their occurrence in vesical urine must be rare. In all staining methods the acid-fast organisms which can occur in distilled water must be excluded.

SMEGMA BACILLI

Of all organisms, however, the most important for us in relation to differential diagnosis is the smegma bacillus. Careful work has shown that no staining methods differentiate tubercle and smegma bacilli. Recent work further reveals the fact that smegma bacilli are difficult to cultivate directly from the patient. In fact, some hold that real smegma bacilli cannot be cultivated; that smegma contains two varieties of acid-fast organisms, only one of which can be grown. It is of some importance to know the frequency with which smegma bacilli occur in nature. Brereton and Smith[1] in 126 insane or uncleanly patients found red staining bacilli in 85 (67.5 per cent.) after decolorization by 25 per cent. sulphuric acid, while they occurred in only 19 (22 per cent.) of these patients after methylene blue had been used as a counterstain after decolorization. They were present in 13 per cent. when decolorized by acid alcohol or Labarraque's solution (in 16 (13 per cent.) of 119 when decolorized by acid alcohol and in 16 (13 per cent.) of 117 when decolorized by Labarraque's solution). In a second series of 20 men of ordinary cleanly habits, smegma bacilli were present in 13 (65 per cent.) after the use of sulphuric acid only (25 per cent.), and 2 (10 per cent.) after counterstaining.

Smears from the anterior urethra (fossa navicularis) were made by Young and Churchman[2] in 24 patients and smegma bacilli found in 11 (46 per cent.), while of 6 patients, smegma bacilli were found in the urine of 5. The urine in the bladder at necropsy, or smears from the bladder wall, were negative in 50 cases. The posterior urethra was negative for smegma bacilli in the 6 cases examined. This work led Young and Churchman[2] to advise thorough cleansing of the penis and rinsing with large quantities of water, as well as careful irrigation of the anterior urethra. The urine they say should be passed in three glasses and only the third used in examination for tubercle bacilli. This technic, they believe, will fully exclude all smegma bacilli from the urine and acid- and alcohol-fast bacilli present can be considered tubercle bacilli. In women, catheterization of the ureters must be practiced.

The differentiation of tubercle and smegma bacilli by methods of cultivation are said to be very unsatisfactory on account of the difficulty in getting smegma bacilli to grow. Brereton and Smith question whether the true smegma bacilli have ever been successfully cultivated. Mr. Petroff and I have found out that the so-called smegma bacilli, which grow luxuriantly, cannot resist treatment with normal sodium hydroxid (4 per cent.) solution for fifteen minutes, which procedure affects tubercle bacilli little if at all. Of course all differential methods, dependent on cultivation of an organism, possess the inherent weakness that the organism may be dead. This argument was advanced as the explanation of the inability of all observers to grow tubercle bacilli directly from the feces, or, indeed, to infect guinea pigs with the tubercle bacilli contained in the feces. Since both these ends have been accomplished, the foundation for such arguments has been materially weakened. Of course until a satisfactory method for cultivating the true smegma bacilli has been discovered, it is useless to base any diagnostic methods on a procedure which depends on their growth; but Petroff's new "egg-meat-juice-gentian-violet" medium will enable us to grow tubercle bacilli readily. If at the end of ten days or two weeks no growth takes place in a tube which has been inoculated with a sediment containing acid-fast bacilli, we are almost justified in concluding that they are not tubercle bacilli.

VALUE OF STERILE CULTURES

In 40 out of 42 cases of urogenital tuberculosis Suter[3] obtained no growth on inoculation into the usual mediums of the carefully collected urine. The presence of symptoms of cystitis and the absence of growth on inoculation of catheterized urine into the ordinary mediums is, he holds, evidence of renal tuberculosis. Albarran looks on the absence of microorganisms in a "purulent" urine in the same light.

FREQUENCY OF EXAMINATIONS AND COLLECTION OF SPECIMENS

He who would base an opinion on the presence or absence of tubercle bacilli in sputum on the examination of one specimen would be ridiculed. After thinking it over we would all, I am sure, come to the same conclusion in regard to the presence of tubercle bacilli in the urine. That they may occur for a while and then disappear entirely, cannot be denied. The occurrence of so-called "showers" of tubercle bacilli is common knowledge. Even good laboratory men, however, do not always bear this in mind and do not hesitate, in some instances, to deny the presence of tubercle bacilli in the urine after one or two examinations. The same care should be exercised in collecting specimens of urine as of sputum. The patient should be warned that whenever any unusual symptoms supervene he should submit two or three specimens of urine. Such symptoms embrace increased diurnal frequency of micturition, cloudiness of the urine when it is passed, and any unusual sensation connected with the genito-urinary system.

PRACTICAL METHOD OF EXAMINATION OF THE URINE

The most satisfactory method of finding tubercle bacilli in urine is probably that used by Mr. Petroff at the Adirondack Cottage Sanitarium, as follows:

Add to the urine to be examined, which has been acidified with 30 per cent. acetic acid, 2 per cent. of its volume of a 5 per cent. solution of tannic acid. This urine is then put in the ice-chest for twenty-four hours. The precipitate can then be centrifugalized, redissolved with dilute acetic acid, centrifugalized and the sediment placed on slides and stained, or the first precipitate treated with normal sodium hydroxid solution and cultivated.

CONTROL STAINING

A simple point that may aid in diagnosis might be mentioned. The bacilli to be stained may be placed on the same slide with a few typical tubercle bacilli which have been immersed in urine and the two smears subjected to the same methods of decolorization. If the questionable bacilli are decolorized when the control tubercle bacilli still retain the red stain, it is presumptive evidence that they are not tubercle bacilli.

ANIMAL INOCULATION

Many contend, however, and I must confess to a similar tendency hitherto myself, that when acid- and alcohol-fast bacilli are found in urine the sediment from large quantities of freshly collected urine should be inoculated subcutaneously into several guinea pigs, which should become tuberculous before a diagnosis of tuberculosis is made.

I saw several years ago a young married man, about 28, who while perfectly well, before the consummation of marriage, for eugenic purposes consulted a physician. His urine contained albumin and a specialist found tubercle bacilli in the urine from the right kidney. A second specialist could not make such a diagnosis, but suspected it, and referred the patient to me for general treatment. His lungs were negative. We centrifugalized a large quantity of urine (not obtained by catheter) and found a great number of acid- and alcohol-fast bacilli, like typical tubercle bacilli. Inoculation of this sediment into guinea pigs produced no tuberculosis. He gained in every way and returned to work, but about six months later developed a tuberculous epididymitis and the epididymus was removed. I question now whether his right kidney is not tuberculous.

A. DISCOVERY OF TUBERCLE BACILLI IN THE URINE ON ROUTINE EXAMINATION

The discovery of tubercle bacilli in the urine of an individual without any symptoms referable to the genito-urinary tract suggests much of interest. For tubercle bacilli to be present in the uncontaminated urine they must have, in some manner, gained entrance into the body. It is to-day well established that they can enter the body and leave no discoverable lesion at the portal of entry. It would be but a step farther to go to picture that, if this can occur, their exit from the body without discoverable lesion can also take place. Indeed, this would seem to occur through the liver, for Calmette has found tubercle bacilli in the bile of experimental animals, which had, as far as I recall, no discoverable lesion in the liver or gall tract. If the liver permits the transmigration of tubercle bacilli, it would appear from analogy that the kidney might also. That this can take place in man appears now to be settled. A case has been reported by Rist and Kindberg[4] in which a patient with asystole of aortic origin died of an intercurrent erysipelas. No tubercle bacilli had been found in the sputum, even after animal inoculation, but on two separate occasions injection of urine had caused tuberculosis in guinea pigs. A necropsy revealed an apical tuberculous scar in one lung, but in no other organ could any tuberculosis be found. Many fragments of organs, including the kidneys, were introduced into guinea pigs without producing tuberculosis. The explanation advanced by the authors is that the tubercle bacillemia was taken care of by the kidneys, which excreted or permitted the tubercle bacilli to pass. Kuester had a somewhat similar case in which occurred convulsions, hemorrhage from the urinary organs and tubercle bacilli in the urine, while both kidneys were found free from tubercle.

PATHOLOGIC CLASSIFICATION OF TUBERCULOUS RENAL INFECTION

At this point I might mention the pathological classification of Jousset.[5] He divides tuberculous renal infection into three groups:

1. Those with specific pathologic changes:
   a. Massive tubercles (cheesy). (Surgical.)
   b. Miliary tubercles (this includes the vast majority found at necropsies).
2. Those with non-specific pathologic changes varying from hyperemia to interstitial changes.
3. Those without pathologic changes. No variations from normal or a very slight epithelial lesion.

While speaking of pathology, I might say that experimental work all tends to show that in the genito-urinary tract the infection is descending and not ascending. A few clinical cases suggest, however, that ascending renal tuberculosis can occur when tuberculous ulceration takes place about the mouth of the ureter and the urine is partly or completely dammed back.

Considerable work has been done in studying the urine of patients with pulmonary tuberculosis, to discover whether or not it contained tubercle bacilli. From what has been said it is readily seen that the only results to which no objections can be offered are those in which animal inoculation has been practiced.

In nine of eighteen cases of severe pulmonary tuberculosis, Foulerton and Hillier[6] found tubercle bacilli in the urine by inoculation into guinea pigs, but not by microscopic examination. Six of these nine died later and the kidneys showed no signs of tuberculosis.

---

[4] Rist and Kindberg: Presse méd., 1914, p. 177.
[5] Jousset: Baumgarten's Jahresb., 1904, p. 646.
[6] Foulerton and Hillier: Brit. Med. Jour., 1901, ii, 774.

Bertier[7] believes that when the tuberculosis is at a standstill, tubercle bacilli occur less frequently in the urine, but agrees with the finding of Foulerton and Hillier that bacilluria can occur without renal changes.

Cunningham[8] found six out of sixty-six patients with pulmonary tuberculosis to yield urine containing tubercle bacilli on animal inoculation. Bernstein,[9] repeating this work, found ten positive cases in 100 patients with pulmonary tuberculosis without symptoms referable to the urinary tract. Six of these patients had no albuminuria and three no cystoscopic changes, but in three the urine contained pus cells.

In 104 collected cases, thirty-seven among children, positive results were obtained on inoculation in eleven, or 10 per cent. One or more of these, however, may have had renal tuberculosis. In 52 cases at the Adirondack Cottage Sanitarium positive results were noted in two instances, both ill patients, one of whom has recovered and one has died. The patient who recovered showed urinary symptoms of some renal disease, while the patient that died showed none. None of these patients at the Adirondack Cottage Sanitarium presented any symptoms referable to the genito-urinary tract.

As far as I can determine, the presence of tubercle bacilli in the urine of these patients who present no discoverable pathologic changes in the genito-urinary tract does not necessarily signify clinical renal tuberculosis, for tubercle bacilli may pass into the bladder without injury to the kidney.

B. TUBERCLE BACILLI IN THE URINE OF PATIENTS WITH SYMPTOMS REFERABLE TO THE URO-GENITAL TRACT

The presence of symptoms referable to the uro-genital tract gives a very different significance to discovery of tubercle bacilli in the urine. Without question tubercle bacilli in the urine come most frequently from the kidney, and for this reason, as well as for the fact that vesical tuberculosis is most frequently secondary to renal tuberculosis, I shall at first speak of renal tuberculosis.

FREQUENCY OF RENAL AND PULMONARY TUBERCULOSIS

Renal tuberculosis is not rare in patients with pulmonary tuberculosis. Fischer[10] found at necropsy histologic tuberculous changes in the kidney of 50 (67 per cent.) of 74 cases of chronic pulmonary tuberculosis. Walsh[11] found tuberculous changes in the kidney of 35 (58 per cent.) of 60 patients dying of pulmonary tuberculosis. Posner[12] discovered 25 per cent. of renal tuberculosis in 519 necropsies on subjects with pulmonary tuberculosis, while Israel[13] noted that 50 per cent. of his necropsies on renal tuberculosis revealed pulmonary tuberculosis as well, and Kelynack 70 per cent. When it is considered that uro-genital tuberculosis is practically always hematogenous and secondary to some other tuberculous foci, however slight, and that the vast majority of the so-called "primary cases" are only those in which the secondary overshadows the primary focus of infection, such figures are not astonishing.

DO TUBERCLE BACILLI OCCUR IN THE URINE BEFORE SYMPTOMS ARISE?

Whether tubercle bacilli occur in the urine before symptoms develop has not been proved, but from the foregoing statements I believe that it is not improbable that tubercle bacilli may exist at infrequent intervals in the urine long before any symptoms occur. This, of course, raises the question of the significance of the presence of tubercle bacilli in the urine without symptoms; and while they can occur without renal changes, I believe it is far safer for us, after a negative roentgenogram, to keep the patient under observation for several years.

THE TIME OF DIAGNOSIS

The symptoms that suggest renal involvement in a person hitherto healthy are usually rather well marked when he consults a physician. Of 212 patients at the Mayo Clinic, 71 per cent. had a duration over one year, 17 per cent. over five years and 6 per cent. over ten years. Only 10 per cent. applied with a duration of disease of less than six months (Braasch[14]). When a patient with tuberculosis develops albuminuria, renal tuberculosis should be thought of at once, and it has long been our custom at the Adirondack Cottage Sanitarium to search the urine of such patients for tubercle bacilli and to inoculate the sediment into a guinea pig. The general symptoms of tuberculous poisoning can in these cases be easily attributed to the tuberculous condition present elsewhere. It must not be forgotten that renal tuberculosis is nearly always a hematogenous infection, secondary to a more or less veiled tuberculosis in another part of the body. The diurnal irritability may in such patients be explained by the increased amounts of milk and water taken. The blood pressure is not raised.

The history of a case in which I was at fault may possibly be of assistance to others:

> The patient, who was very nervous, had been under my care for some years for an extensive pulmonary tuberculosis. He had complained at different times of slight malaise and of discomfort or pain in the lumbar region. His urine, previously normal, first showed a trace of albumin and a few granular casts in June, 1911. In August there was pus and the reaction was acid. This continued, and two or more inoculations were made into guinea pigs, which developed no tuberculosis. In February, 1912, he complained of increased expectoration, some premature systoles, but said he had had no symptoms from his kidneys. In April, 1912, another guinea pig was inoculated and developed tuberculosis. Tubercle bacilli, which had not been found before, then appeared in the urine and were found by catheterization to come from the right kidney. The left kidney was normal. Cystoscopy showed a slightly affected bladder, with some congestion at the right ureteral orifice. The kidney was removed in June, 1912, and found extensively involved, as well as the ureter. The wound was closed, but broke down and healed finally about December, 1913.

This case is a good example of what may occur when one waits for tubercle bacilli to appear in the urine. Roentgen-ray picture might have been of considerable assistance.

THE URINE IN RENAL TUBERCULOSIS

Pyuria, with an acid urine, hematuria, pain referred to the kidney, a nodular enlargement of the epididymus or prostate, are all of great importance in diagnosis and should lead to the repeated examination of the urine for tubercle bacilli. Here, however, as in the sputum examination, a positive finding far outweighs a negative. I have spoken of the "showers" of tubercle bacilli which may occur at infrequent intervals in the urine. On the other hand, we must not forget that involvement of the ureter may lead to its closure, a procedure which performs, so to speak, autonephrectomy. A tuberculous kidney may, therefore, have no opening into the bladder and the tubercle bacilli are dammed up.

A CASE OF AUTONEPHRECTOMY

A case reported by Renton[15] is of considerable interest in this connection. A man, aged 27, giving a history of marked vesical symptoms for three or four years, very ill and thin, without any recollection of pain in the renal regions, showed on cystoscopic examination a greatly retracted bladder, lined with a white caseous-looking deposit. No tubercle bacilli were found in the urine. Ten days later he died. On one side autonephrectomy had taken place; on the other side the kidney was tuberculous and largely destroyed. The bladder was completely covered by caseous tubercle bacilli. To think that a good man could find no tubercle bacilli in the urine of such a patient sounds a note of warning for us all. But some excellent men have failed to find tubercle bacilli in 50 per cent. of their cases, and others have discovered them only in 20 to 40 per cent. Tubercle bacilli may occur, however, in the urine only at rare intervals for several years, and when constantly present would indicate to me that if they come from the kidney a rather extensive ulceration has occurred.

THE URINE IN ACUTE MILIARY TUBERCULOSIS

It is of interest to note the occurrence of tubercle bacilli in the urine in cases of acute general miliary tuberculosis. Churchman[16] apparently believes that tubercle bacilli occur in the urine of nearly every case of this type, while they may be difficult to find in the sputum.

RADIOGRAPHY

Radiography[17] is probably of value in diagnosis only when the renal tuberculosis has reached an advanced stage, and in one of the cases just mentioned might have been of great value.

SPECIAL EXAMINATIONS

When in the urine of a patient who has diurnal irritability, slight albuminuria, slight pyuria, lumbar pain, with or without hematuria or nodular enlargements in the epididymus or prostate, tubercle bacilli are found, a diagnosis of tuberculosis of the genito-urinary tract should be made and an endeavor to exclude renal tuberculosis attempted. A careful manual examination of the epididymus, spermatic cord, prostate, seminal vesicle and kidneys is called for. A cystoscopic examination should be performed by an expert. Buerger, of New York, has recently found that a slight edematous puffiness at the orifice of a ureter is an indication of renal tuberculosis on that side, and has shown that the edematous tissue may contain tubercles. Catheterization of the ureters will show whether one or both kidneys are involved. It is usually unilateral at first. Functional tests will prove the efficiency of the affected and unaffected kidneys. It must not be overlooked that the enlarged kidney may be the one that functions.

TREATMENT

Before closing I might add a word about treatment. I have long advocated for all active, and for any tuberculous process for a time, functional rest. I believe it is impossible to give a tuberculous kidney functional rest. In the majority of instances I believe this seriously affects the chances of cure, though when a slight tuberculous ulceration occurs in the pelvis of the kidney, which I believe is rare, I can see no reason why it might not heal. For this reason it seems to me that, *theoretically,* renal tuberculosis of any degree should be treated by nephrectomy. Only twenty-five years ago such advice was violently opposed, but to-day conservative surgical opinion is in favor of this treatment and many believe that tuberculin, the hygienic-dietetic treatment, or, in fact, treatment by any medical means, has little to offer, as extension of the disease to other parts may take place during such treatment. After nephrectomy, however, tuberculin is of great value.

COMPARISON OF MEDICAL AND SURGICAL TREATMENT

The report of Wildbolz[18] (1912) on 316 cases of renal tuberculosis treated by non-surgical methods is enlightening. Of these patients 70 per cent. died within five years and only 10 per cent. are alive more than five years after the commencement of the disease. Only one case was well in every respect. Compare this with the results at the Mayo Clinic where nephrectomy was practiced. (Braasch.) The operative mortality was 2.9 per cent. of 203 cases. Excluding recent and untraced cases, we have 142 to be considered of which 98 or 69 per cent. were well or greatly improved more than one year after operation, while 13 per cent. had no relief from the vesical symptoms. When it is considered that renal tuberculosis in nearly 90 per cent. of all cases attacks one kidney first, the danger of delay in operation is evident.

SPONTANEOUS HEALING

Spontaneous healing has been said to occur but when Albarran challenged the French surgical society to produce one such case, none was forthcoming.

Elkhorn[19] has reported a case of so-called spontaneous cure. In 1901 the patient had pronounced symptoms of renal and vesical tuberculosis, with numerous tubercle bacilli in the urine. In 1907 he was apparently perfectly well, but in 1909 while in the hospital for treatment for worms, with a normal urine, cystoscopy showed a pyonephrosis. At operation the kidney was found totally destroyed and the pus-like material produced no tuberculosis in guinea pigs. I have gone into the details of this case to illustrate how "spontaneous healing" usually occurs in renal tuberculosis. The kidney is destroyed, becomes a pultaceous mass, the ureter is closed and the symptoms may, as in this case, disappear. I believe that tubercle bacilli were exceedingly rare in the kidney sack, or indeed may have entirely disappeared.

The bladder is involved in 80 per cent. of all cases, but at first the lesion may be slight or the symptoms partly reflex. After nephrectomy the vesical disease usually clears up unless it has advanced too far, when the condition is exceedingly deplorable and difficult to relieve.

THE URINE IN TUBERCULOSIS OF THE GENITAL TRACT

The occurrence of tubercle bacilli in the urine of patients with tuberculosis of the epididymus, the seminal vesicles, or the prostate, has never been thoroughly investigated. Marwedel found tubercle bacilli in the urine in four cases of prostatic tuberculosis. My own experience is very limited, but in three cases no acid-fast rods were found in the urine. When the prostate or seminal vesicles are involved, massage may produce a secretion containing tubercle bacilli. The constant presence of the occurrence of tubercle bacilli in large numbers would suggest tuberculosis of the urinary tract as well.

Fortunately the diagnosis of tuberculosis in the genital tract rarely depends on the discovery of tubercle bacilli in the urine. An enlarged globus major with a thickened or slightly enlarged seminal vesicle or irregular or nodular prostate in a patient with a preexisting tuberculosis can be diagnosed as tuberculous. Barney's[20] paper on this subject should be consulted.

CONCLUSIONS

1. No staining method differentiates absolutely tubercle bacilli from smegma bacilli, but cultural methods may aid greatly.
2. Animal inoculation, with the production of tuberculosis, is an absolute test, but of value only when positive.
3. The same care about the collection of urine should be exercised as about the collection of sputum.
4. Tubercle bacilli can be excreted through apparently normal kidneys.
5. Radiography may aid in the quick detection of caseous foci when the urine contains no tubercle bacilli.
6. Spontaneous healing is often fictitious.
7. The final, and often the best, treatment for renal tuberculosis on diagnosis, is nephrectomy followed by the use of tuberculin.
8. Tubercle bacilli occur in the urine in genital tuberculosis usually late in the disease and are consequently of little aid in diagnosis of the condition.

Infectious Diseases an Unnecessary Waste.—Sir Frederick Treves believes that the time will come when hospitals for infectious diseases will be empty and not wanted. This is to be accomplished by hygiene. The fight is against millions of microbes, and the weapons are sanitary regulations, municipal government, the sanitary inspector and the health officer. The mystery of the ancient doctor, with his long words and extraordinary prescriptions, is passing away. The multitude of shelves of bottles which surrounded lives also is passing away and being replaced by simple living, suitable diet and plenty of sun and fresh air. The time will come when it will be as anomalous for persons to die of scarlet fever, typhoid, cholera or diphtheria as for a man to die of a wolf's bite in England. Personal hygiene is only beginning to be generally exploited. It is manifest destiny that a wise economy of vitality will sooner or later be practiced. Waste of vital resources is as irrational as waste of natural resources. Neither is inexhaustible and both must be conserved. Thoughtlessness and ignorance are the reasons for the appalling waste of both now going on.—Irving Fisher, "Report on National Vitality."

FAMILIAL SYPHILITIC INFECTION IN GENERAL PARESIS [*]

ROBERT H. HASKELL, A.B., M.D.
ANN ARBOR, MICH.

In view of the fact that so little definite information concerning the importance of familial syphilitic infection in paresis has been brought before the American medical public, it has been thought desirable to present briefly certain observations which we have been able to make in this connection during the past three years.

The material on which our observations have been made includes, first, fifty-five clinically unquestionable cases of general paralysis in married individuals admitted during this time in which we have been able to test the presence of syphilitic infection in the other mate, and secondly, eighty-six cases in which the anamnesis concerning intimate family matters of absolute sterility, pregnancies with early abortions, total number of living-born children, with additional abortions, miscarriages, etc., could be accepted without question.

We have been able to examine the blood serum of the conjugal mate in fifty-three married paretics. Seventeen, or 32.7 per cent., of these cases showed a positive Wassermann reaction. Although this figure is sufficiently high to be striking, it yet does not represent the whole situation. One wife, acknowledging a severe infection following a lip chancre, had had careful treatment and presented at the time of our examination a negative Wassermann reaction. The first wife of a patient, whose second mate now has a strongly positive reaction, herself died of syphilitic disease. Of two female paretics, the husband of one preceded her in the development of paresis by about one year, while the husband of the other died of tabes about two years before. Since both of these husbands must have had syphilis, they should be added to the total. Although there are other possible factors, such as, for example, a wife showing a repeatedly negative Wassermann reaction and yet a history of repeated abortions without living children, or where the wife has a negative reaction but with children showing a positive Wassermann, which would justify assuming an additional number to swell this figure, at the present time we will add only these unquestioned cases. These additions show that in the families of fifty-five paretic patients there is a total of at least twenty-one mates infected with syphilis.

Separating this group into the two sexes, we find that in forty-nine cases in which the husband is paretic, seventeen wives are infected with syphilis; in six cases in which the patient is a woman, there are four husbands who are known to have syphilis.

While these figures are high, they are not greatly higher than other investigators have found and, as already suggested, probably underestimate rather than exaggerate the real situation. In a study of fifty-four cases of married paretics Plaut and Göring[1] found the other mate showing a positive Wassermann reaction in 32.6 per cent., a slightly smaller number than our figures of 38.18 per cent. Hauptmann[2] includes among forty-three cases where he investigated whole families serologically, eighteen cases of paresis in which he found a positive Wassermann in twelve mates, or the enormously high figure of 66⅔ per cent.; but, inasmuch as he picked these cases for a special purpose and did not take them as they came, as in Plaut and Göring's study and in our own, this figure does not concern us.

---

[*] From the Psychiatric Clinic, University of Michigan.

[1] Plaut and Göring: München. med. Wchnschr., 1911, No. 37, p. 1959.

[2] Hauptmann: Ztschr. f. d. ges. Neurol. u. Psychiat., 1912, viii, 36.

The number of these infected mates who had previous knowledge of any infection, or who could tell us of any suspicious signs of secondaries, was the extremely small figure of two. Only one of them had had any antisyphilitic treatment. The matter of regularly mild or no skin and mucous membrane lesions appears to be about as common as similar observations on paretics themselves.

At the time these paretic patients entered the hospital, excepting the two where the other mate was known to have already had paresis and tabes, respectively, there was only one case in which ordinary clinical methods, such as could be used in examining a visitor, gave sufficient grounds for assuming organic disease of the central nervous system in the conjugal mate. This was in a wife with the Wassermann reaction on her blood strongly positive, apparently regularly moderate and occasionally excessive in her alcoholic habits, who showed a slightly sluggish reaction of her pupils to light and unequally diminished knee jerks. She showed some difficulties in her speech, an ataxic tremor in her writing, mild defect in retentive memory, spreading of impulses through her facial muscles under mild emotion, and some difficulties in solving involved mathematical tests. Though one appears justified in making a clinical diagnosis of conjugal paresis in her case, yet in view of her showing signs of mild alcoholic intoxication on each of two visits, in itself a very significant fact, until we shall have been able to examine her cerebrospinal fluid we shall not include her further in our statistical consideration.

It so happens that in our material we are quite certain in each case which mate was infected with syphilis before marriage, and from now on in this paper that individual will be spoken of as the infecting member. In only three cases was the woman the first infected; in two of these the serum examination on the husband was negative, while in the third the reaction was positive.

The relation of already developed metasyphilitic disease in the other mate is interesting. In one case both mates were paretic; in the other case the original infecting mate was tabetic, with the infected member paretic. How many metasyphilitic mates should we expect? This query leads us immediately into the big question of the existence of a lues nervosa, but it is well perhaps merely to state the results of some other careful observations. Mattauschek and Pilcz,[3] from observations on 4,134 army officers infected with syphilis between 1880 and 1900, found 4.67 per cent. to have developed paresis by 1912 and an additional 1.6 per cent. to have developed tabes, a metaluetic total of 6.27 per cent. These figures concern, however, a rather specialized group and one exposed to many of the factors supposed to tend to metasyphilitic disease. Pick and Bandler found that among 2,066 syphilitics coming to the Prague Skin Clinic during 1879-1899, twenty-eight had become paretic in 1904, a percentage of 1.3. O. Fischer[4] separates these into the two sexes and shows that among 1,178 men 25 had paresis and 12 tabes and among 888 women 3 had paresis and 2 tabes, or 3.7 per cent. of the men and 0.55 per cent. of the women had in that interval developed a metaluetic disorder. What proportion of these had obtained their syphilis in the first place from one who had, or later developed, a metaleutic disorder is unknown. In his own 500 cases of paresis Fischer had 395 married individuals. Among the 319 men 1 wife developed paresis and 2 tabes, while among the 76 women 5 husbands had paresis and 2 tabes; that is, a total of 10 metaluetic individuals, or 2.5 per cent. of the infected mates developed some metaluetic condition. Mönkemüller among 741 married paretics found 18 cases, or 2.14 per cent., of conjugal metaluetics. These figures, even when applying only to the cases of conjugal paresis, 6 in Fischer's cases and 14 in Mönkemüller's, are considerably higher than Hannard and Gayet[5] found among 2,429 married paretics in two French institutions where only 23 mates developed conjugal paresis.

In our material, starting with 51 metaluetic husbands, whom we are justified in assuming to have been the infecting agents, and of whom we grant that possibly one was only a tabetic, we find that among 19 infected wives 2 have already developed general paralysis. In this smaller number of cases the percentage of wives to have already developed paresis is 3.9 per cent. when figured on the entire number, but when figured on the number of wives shown by the Wassermann reaction to be infected with syphilis, it reaches the astounding figure of 10.5 per cent. It so happens that this figure agrees exactly with the percentage Fischer reaches in studying his 76 female paretics, where he assumes, rightly or wrongly, that all these wives got their syphilis from their husbands after marriage.

We have further been able to study the matter of sterility and the number of abortions and living-born children in 86 cases in which the accuracy of the anamnesis, furnished by the wife or husband of the patient and confirmed in many cases by the patient, could be definitely depended on. The conditions found are clearly illustrated in the accompanying table.

DATA CONCERNING FERTILITY IN PARETIC MARRIAGES

	Total Number	Sterile Completely	Abortions Only	Total Number of Abortions	Living-Born Children
Male G. P...	76	22	10	43	110
Female G. P.	10	6	1	1	13
Total	86	28	11	44	123

This table shows that of 86 marriages among paretics, 39, or 45.4 per cent., were absolutely childless. Of this number 28 marriages, or 32.5 per cent., were completely sterile, while the additional 11, or 12.7 per cent., resulted only in abortions. This total number agrees almost exactly with Heubner's figures of 45.7 per cent. of childless marriages, although his percentage of completely sterile marriages is about 7 per cent. higher. This percentage is considerably higher than Kraepelin's[6] findings of about 18 per cent. of unfruitful marriages in his Munich material, which is not much higher than the figure for the whole German population, and yet distinctly lower than Regis gives, who assumes that three-fourths of paretic marriages are childless.

Even more interesting and startling is the matter of the living-born children. The average number of living-born children in this group is 1.4 to each family. If we consider only those families with living-born children, we find the average to be 2.24 children per family. In this group, however, are included 2 instances in which there is the unusually large number of 10 and 12 children, respectively. If we exclude these two abnormally large families we find that 75 families of male paretics have 98 living-born children and 9 families of female paretics have 3 living-born children. The average would then become 1.2 children per family, or where the father was paretic, 1.3 children per family, and where the mother was paretic only 0.3 children per family. Our number of paretic wives, we grant, is extremely small and not sufficient in itself to warrant drawing conclusions from it alone, but it is found quite generally that when the mother is the paretic the influence on the matter of sterility, number of abortions and small number of living-born children, together with their character, is more marked than where the father is paretic.

Further study of the histories of these 84 families with 101 living-born children shows that at the time the paretic patient entered the hospital, in this series averaging a period of 11.6 years after marriage, 20 children of this extremely small total of 101 died. Usually these deaths were in early infancy, as in the following instances, in which definite statements are noted: "1 immediately and 1 at the end of the first day," "1 at the end of the first week and the other of hydrocephalus at 5 months," "1 of spasms at 5 weeks," "1 of convulsions in early infancy." Subtracting these 20 children already dead from the total number, we find that in 84 families after a married life averaging 11.6 years, there were living only 81 children or less than one living child per family.

There is no statistical compilation of similar conditions in the general population which will allow satisfactory comparison of these figures. The nearest approach to this end is the tables of the United States Census in which we find that the average family in the State of Michigan in 1910 consisted of 4.3 individuals. With the two parents subtracted from this figure it leaves a total of 2.3 living children per family of the entire population. We do not know the average length of married life in these families entering into this general statistical compilation, but it would appear quite justifiable to assume that it at least equaled the period of 11.6 years found in our present series. Granting this assumption, we are able to conclude that the number of living children in the average family throughout the State of Michigan is 2.38 times as large as the average number of living children in the families of our series of paretic patients.

It would be desirable to know just when the original syphilitic infection occurred, the position that each pregnancy and miscarriage bore to that time and the relation which the three different types of marriages outlined above bore to this varying interval before marriage. All who try to obtain accurate histories from this type of patients know such information is very unsatisfactory at best, and inasmuch as we are not at this time going deeply into the matter of the character of the living offspring, we have purposely minimized its importance.

Our examinations of the serum of the children in these cases have not as yet been extensive enough to warrant drawing any conclusions. Plaut and Göring found among 100 children of their 54 cases a positive Wassermann reaction in 26 instances. They found in some families children showing a positive reaction where the mother's serum gave a negative reaction, and again, some children with positive and others in the same family with negative reactions. Similar observations can be found in Hauptmann's series and in our own cases. Although only 26 per cent. of Plaut's cases gave serologic evidences of syphilitic infection, 45 per cent. showed some defect in their physical conformation or signs of a psychopathic constitution, although as a rule they were intellectually well gifted. In many cases these defects are degenerative physical states no different from similar conditions found in children in whom other toxic agents, such as alcohol, have impaired the normal development of the germ plasm. The negative reaction in such cases, Hauptmann, drawing on bacteriologic distinctions, would explain as due to the condition being purely an intoxication, and assumes such children not to be infected with the treponeme. Such children do not show signs of definite specific disease. Theoretically they should not later develop juvenile paresis or even non-nervous specific disease. Whether they can later develop a primary sore is highly interesting. It is assumed that the Wassermann reaction and other of the four signs long precede the development of paresis. Since juvenile paresis and other evidences of lues hereditaria may not appear until the second and third or even fourth decade, it will require longer observation to prove whether this assumption holds true. Since this problem is very closely allied to the influence of constitutional syphilis on the descendants, we will leave it with the statement that competent observers have found about one-fourth of the living children of paretics to be actually infected with syphilis and approximately another fourth to show definite evidences of degenerative influences in their physical or mental constitution.

The number of cases in our series is admittedly small, but since they are taken as they came over a space of three years, and since they agree very closely with similar deductions made from larger numbers, one is justified in believing that they present a truthful picture.

With so much said, the next pertinent question is, What are you going to do about it? We have already commented on the pitifully small number of the infected mates of our paretics who had any knowledge of their disease. The same condition obtains, to be sure, in a large majority of all paretics. Treatment as ordinarily carried out with pills, even in those cases that are recognized, is the harmful factor. Some competent syphilologists have said that in those cases in which they have had control of the treatment of their syphilitics from the beginning, they have never seen tabes or paresis develop. Recent years have shown an unusually high percentage of early involvement of the central nervous system even in the secondary stages, particularly from the work of Ravaut and of Wile. Correct diagnosis of the syphilitic condition should be made and careful, persevering treatment given, with attention to the newer findings in the cerebrospinal fluid. If these pathologic changes do not permanently disappear under acceptable mercurial and salvarsan treatment, direct intraspinal introduction of salvarsanized serum in some form, with proper Wassermann control before permitting marriage and then similar careful observation, serum examinations and, if necessary, treatment in the case of the wives and children of all syphilitics, should theoretically offer some relief.

CONCLUSIONS

The large number of 38.18 per cent. of conjugal mates of paretic patients is shown to be infected with syphilis. In most of these mates the condition courses unrecognized as lues latens.

A pitifully small number of them ever receive treatment.

The proportion of these infected mates who later develop paresis appears to be higher than those who receive their infection from non-metasyphilitic sources.

The number of completely sterile marriages in syphilitic families in which one individual later develops paresis is abnormally high, constituting 32.5 per cent. This percentage is higher when it is the female mate that later becomes a paretic.

The number of marriages in which repeated pregnancies result only in abortions is likewise abnormally high, constituting in our series 12.7 per cent.

Of our series of eighty-six marriages 45.3 per cent. were absolutely childless.

Among 167 pregnancies there were forty-two abortions, miscarriages and stillbirths.

Among 123 living-born children twenty had already died before their eleventh year.

The number of living children per family is abnormally small.

A large number, in some investigations reaching as high as 25 per cent., of these children are actively syphilitic.

An equally large additional number show signs of degenerative physical conformation and psychopathic tendencies without a positive Wassermann reaction.

Much of all this is preventable.

State Psychopathic Hospital.

A REVIEW OF THE PRINCIPAL METHODS USED TO STANDARDIZE BACTERINS (BACTERIAL VACCINES)

WITH SPECIAL REFERENCE TO THE USE OF THE HEMOCYTOMETER *

C. P. FITCH, M.S., D.V.M.
ITHACA, N. Y.

The use of bacterins in the treatment and prevention of disease has steadily increased since their introduction by Wright in 1902. "Vaccine therapy," so called, is now used by nearly every practitioner of human or veterinary medicine. Much more attention, however, has been paid to the extension of the application of this branch of medicine than to the study of its underlying principles and the perfection of its technic. One of the first requisites is an accurate and reliable method of estimating the number of dead bacteria inoculated. There are a few workers who will doubtless claim that it is quite immaterial whether a few million bacteria, more or less, are injected, and furthermore, that no method is absolutely accurate. These criticisms are not confirmed by careful scientific work. Those who are familiar with the use of bacterins know that often their injection is followed by unexpected results due to the toxicity of the bacterin, the idiosyncrasy of the patient or too large a dose, further, that while it is true that probably no method gives the exact number of bacteria, certain procedures lead to more accurate results than others.

During the last few years, I have prepared many bacterins for human and veterinary use. In their preparation the great inaccuracy of the methods of standardization has been thoroughly impressed on me. The more reliable methods were used and finally one was adopted, that is, the hemocytometer, which seemed to give by far the most reliable results. This method has been employed for the past three years.

On the publication of the article by Glynn, Powell, Rees, and Cox,[1] in which they give the results of very careful comparisons of the different methods, these results were compared with those obtained by me and found to agree in practically every instance. The technic which gave the most reliable results with them was the one used by me with several minor modifications. So far as known this method is not widely used in this country and it has been thought advisable to review the different methods of bacterin standardization with the relative advantages and disadvantages of each.

I. WRIGHT'S METHOD

Wright[2] first described his method in 1902. In its original and simplest form it consists in mixing measured and usually equal volumes of bacterial suspension and normal human blood with a small capillary pipet on a glass slide. From this mixture films are made on glass slides, stained, and a number of fields are examined microscopically. The number of bacteria and corpuscles are counted in each field and the ratio of the bacteria and red corpuscles found. The average number of red corpuscles is known to be 5,000,000 per cubic millimeter in a normal individual. Therefore, if there are two bacteria to each corpuscle in the different fields then the bacterial suspension is assumed to contain 10,000,000,000 per cubic centimeter. Allen[3] modified this method by using two or three volumes of a 2 per cent. sodium citrate solution as a further diluent for the bacterial suspension and blood. This was employed in order to prevent coagulation of the blood during the mixing process. He also used 5,500,000 as the average number of corpuscles per cubic millimeter. Nearly all of the stock bacterins now on the market are standardized by this latter modified method.

The criticisms of Wright's methods are many, among them we quote from Glynn, *et al.*:

> Wright's standard of comparison, namely, 5,000,000 red-blood corpuscles per cubic millimeter, is not altogether accurate; thus Cabot[4] states: "At the level of the sea and in adult life the normal number of red cells per cubic millimeter is about 5,000,000 for men and 4,500,000 for women. This is frequently exceeded in vigorous healthy persons; 6,000,000 is by no means rare among healthy young men, and higher figures are seen occasionally."

[4] Cabot, R.: Clinical Examination of the Blood, Ed. 5, New York, William Wood & Co., 1904.

A practical illustration of this difficulty is afforded by the recommendation of Hewlett[5] to employ 5,000,000 as a standard, and Allen, 5,500,000—an increase of 10 per cent. Muir and Ritchie advise the observer to estimate "the red cells in his blood," which, of course, adds to the labor.

Wright's method is extremely ingenious and simple, and has been of great service to medicine by supplying a rough means of standardization. Many workers, however, have abandoned it as too inaccurate. According to Leishman, its chief defect is "the difficulty in securing a perfect film in which the ratio of germs to cells shall be constant throughout"; he also remarks, "Although at times we obtained results which were controlled by a living count, made by dilution and plating out on agar, we were unable to obtain consistently satisfactory results, and, in the case of broth vaccines, errors of from 50 to 100 per cent. in counts of the same film made by different observers were by no means uncommon."

Harrison states: "Unfortunately, in actual practice the process gives very variable results, and even in the hands of its author it gives figures with a variation of as much as 22 per cent. above and below the average of two counts."

Callison says: "As the technic is usually carried out, however, the result is little better than a good guess. The operator pricks his own finger, rarely going deep enough to allow the blood to flow freely, draws into a capillary pipet some of the blood and some of the bacterial emulsion, and then, by working rapidly, mixes the two as much as possible in order to make a smear before coagulation takes place. A little study of such a smear will demonstrate the inaccuracies that result from counting successive fields of red cells and bacteria. The distribution is freakish, and the thick and thin areas of the smear do not coincide. The worst feature of such a smear lies in the fact that in that part where the stroke begins there is a heavy deposit of bacteria, while in the last part it consists almost exclusively of red cells. No estimate of the concentration of a bacterial emulsion, based on a count of such a smear, can be accurate. Another objection to the method is that it does not seem wise to be constantly pricking the finger while working with bacterial cultures."

II. THE NEPHELOMETER METHOD

This was devised by McFarland[6] and is described by him as follows:

> It consists essentially of a series of standardizing tubes containing a suspension of fine precipitate approximating bacterial suspensions in opacity and a holder for making their comparison easy. The standard suspensions used are precipitates of barium sulphate made as follows: Two solutions, one a 1 per cent. solution of chemically pure sulphuric acid, the other a 1 per cent. solution of chemically pure barium chlorid, are prepared, then the one added to the other so that ten standards are prepared, containing 99 c.c. of the sulphuric acid and 1 c.c. of the barium chlorid; 98 c.c. of the sulphuric acid and 2 c.c. of the barium chlorid; 97 c.c. of the sulphuric acid and 3 c.c. of the barium chlorid, etc. According to the number of cubic centimeters of barium chlorid added, these are denominated 1, 2, 3, 4, etc. About 3 c.c. of each standard solution is sealed in a small test tube, care being taken to use tubes of uniform diameter and also to provide similar tubes for mixing the bacteria to be compared with the standard.
>
> The modus operandi of using the instrument is very simple. The standard tube appropriate to the experiment is selected, well shaken, stood in the left-hand pocket of the instrument and a tube containing sterile salt solution stood in the other. The surface growth of the bacterium to be suspended is taken up with a platinum loop and stirred in, rubbing the bacterial mass on the side of the tube just above the surface of the liquid and gradually adding the fluid to it by tilting the tube so as to avoid suspending masses of the culture. When the mixture appears homogenous a comparison is made by looking through the instrument against the sky. If the density be insufficient, more bacteria are added; if it be too dense, fluid can be added drop by drop from a medicine dropper or, what is better, the tube can be given a few turns in the centrifuge, by which the larger clumps of bacteria are thrown down and compared again. One should not be content with the comparison until the suspension be tried with others of the standard tubes than that which one intends to imitate. It is surprising at times to see how what is thought to be an exact equivalent will turn out to be 1 per cent. more or less dense.

This method was used by McI. Phillips[7] in standardizing the vaccines used to treat poll evil and fistulas in horses. It also was the first method used by me.

The errors in the use of this method are very large. The results obtained were compared with those obtained by the hemocytometer (to be described later) and were found to vary from 25 to 200 per cent. This great variation practically places it outside the limit of an accurate method. I agree with Callison,[8] who says concerning it: "It is only necessary to say that this method is *merely* a *guess*. The density of color in a given emulsion will be affected by many conditions aside from the bacterial content, and no two individuals will agree in their judgment as to the density of a color."

III. WEIGHT METHOD

This method was devised by Wilson and Dickson and is described as follows:

> The combined weight of a rectangular piece of thin platinum foil (1½ inches by 1 inch) and of a small dry test tube is estimated. The bacterial growth is carefully scraped off the surface of the medium and transferred to the platinum foil, which is then replaced in the weighing tube. The latter is now put in a desiccating chamber, which may conveniently be made out of a strong boiling tube, to the orifice of which a rubber cork pierced by two glass tubes is fitted. One of these tubes is attached to a Sprengel pump; the other has a well-fitting stopcock, and is connected with a bulb filled with cotton wool; by this air is gradually admitted when desiccation is completed. The desiccating tube and contents are then placed in a water-bath at 50 C., and the Sprengel pump set working.
>
> Desiccation is complete in less than fifteen minutes, when air is cautiously admitted by way of the stopcock, and the glass tube and foil allowed to cool within the desiccator. They are then weighed and the amount of bacterial growth estimated. The platinum foil is then spread out in a sterile dish, the pestle moistened with salt solution, and the dry growth carefully emulsified, salt solution being added drop by drop. In less than five minutes emulsification should be uniform and complete.
>
> They give the following values in round figures for the number of bacteria in 1 mg. of dried growth of the various bacteria:
>
> | | |
> |---|---|
> | Staphylococcus | 3,000,000,000 |
> | Streptococcus | 3,400,000,000 |
> | *Gonococcus* | 4,500,000,000 |
> | Meningococcus | 3,000,000,000 |
> | *B. coli* | 6,400,000,000 |
> | *B. typhosus* | 8,000,000,000 |
> | *B. pyocyaneus* | 3,400,000,000 |
> | Bacillus of Friedländer | 4,300,000,000 |
> | *M. melitensis* | 14,000,000,000 |

---

[7] Phillips, J. McI.: The Treatment of Suppurative Conditions in Animals by Bacterial Vaccines, Including a Preliminary Report of the Use of a Hyper-Immune Serum in Canine Distemper, Am. Vet. Rev., xxxvi, 1909-10, p. 656.

[8] Callison, J. G.: A Diluting Fluid for Standardization of Vaccines with the Hemocytometer, Jour. Med. Research, 1912-13, xxvii, 225.

They claim that the method is simple, rapid, gives uniform results, and is applicable to all bacteria which grow on solid media, whether they form uniform emulsions or not, and that the subsequent preparation of a uniform emulsion is much facilitated by the rapid desiccation.

This method has not been used by me, as considerable special apparatus is necessary for its application.

IV. PLATE-CULTURE METHOD

This method implies the standardization of bacterial suspensions by agar-plate cultures. The suspension is first filtered and centrifuged to do away with the clumps of bacteria. Dilutions usually 1:100, 1:1,000, 1:1,000,000 and 1:100,000,000 are prepared with sterile salt solution, and from these plates cultures are made. They are incubated at 37 C. (98.6 F.), for from forty-eight to seventy-two hours, and then the colonies are counted.

This method has many serious defects. 1. It is long, tedious and cumbersome, requiring from two to three days before the results can be known. 2. A colony may represent the growth of more than one bacterium, which often happens when the suspension is not perfectly homogenous or when diplococci are contained in it. 3. Some of the bacteria may not grow or may even be dead, so that the number of colonies does not represent the number of organisms contained in the suspension.

In comparing this method of estimating the number of bacteria with the actual counting by the hemocytometer it was found that the plate method underestimated. The variations were from 25 to 150 per cent. and always the plate method gave a less count than the hemocytometer.

These figures agree with those reported by Glynn, *et al.,* who state that the deficit obtained ranges from 50 to 200 per cent. This also agrees with the work of Breed[9] and Brew[10] on the comparison of the microscopic and plate method of counting bacteria in milk. They found that the plate method gave results that were from 5 to 44 times less than those obtained by the direct microscopic method.

From the preceding data it is readily seen that the plate method is not suitable for the standardization of bacterins.

V. GRAVIMETRIC METHOD

This method, as employed by Hopkins,[11] consists in the use of a special centrifuge tube, the end of which is drawn out into a small tip. This is graduated in hundredths of a cubic centimeter. The procedure is the following:

> The sterile cotton filter is moistened with salt solution and the funnel is placed in the mouth of the centrifuge tube. The bacterial growth is washed from the surface of an agar culture with salt solution and transferred with a pipet into the funnel. The filtration serves to remove any particles of agar or cotton that may be taken up and also the larger clumps of bacteria. The tube is then covered with a rubber cap, and, after another tube has been filled to the same point so as to balance, is centrifugalized for half an hour. The salt solution and bacteria above the 0.05 mark are then removed, and 5 c.c. of saline solution are measured into the tube. If the sediment does not reach the 0.05 mark, its volume is read on the scale and enough saline solution is introduced to make a 1 per cent. suspension. The sediment is then resuspended by forcing the salt solution into the tip with a capillary pipet and drawing the mixture in and out of the pipet repeatedly. The suspension is next transferred to a test tube to be killed in the usual manner. The tubes are washed, first in phenol (carbolic acid) and then in distilled water, the fluids being drawn into the tip with a pipet.
>
> It is customary to express the dosage of vaccines in terms of the number of organisms injected. Estimations made by centrifugalizing carefully counted suspensions give the following average values for a 1 per cent. suspension of the organisms commonly used when centrifugalized for one-half hour on a head 18 cm. in diameter, at 2,800 revolutions per minute. Similar values could readily be determined for centrifuges with lower speed:
>
> | | Per Cent. | Billion per c.c. |
> |---|---|---|
> | *Staphylococcus aureus and albus*.... | 1 | 10 |
> | *Streptococcus hemolyticus* .... | 1 | 8 |
> | *Gonococcus* .... | 1 | 8 |
> | *Pneumococcus* .... | 1 | 2.5 |
> | *Bacillus typhosus* .... | 1 | 8 |
> | *Bacillus coli* .... | 1 | 4 |
>
> The pneumocicci used were grown on moist serum agar and had well-developed capsules.
>
> With staphylococci the method gives very constant results as compared with a direct count, as the organisms are uniform in size and pack evenly. With colon bacilli and streptococci the count of a 1 per cent. suspension varies considerably, partly because of the great difference in the size of individual organisms of different strains and partly because of inequality in the packing of the sediment. The weight of the sediment dried to constant weight *in vacuo* gives the best index to the accuracy of the method. On a number of determinations the weight of 0.1 c.c. of staphylococci varied from 28.6 to 34.8 mg., with an average of 31.1 mg.; 0.1 c.c. of typhoid bacilli from 22.5 to 27.0 mg., with an average of 24.7 mg., and 0.1 c.c. of colon bacilli from 10.0 to 17.5 mg., with an average of 13.2 mg.

This method, as its author states, gives but approximate results and when they are compared with those obtained by the hemocytometer vary widely. No attempt has been made to tabulate the comparative results, as they differ between such wide limits.

VI. HEMOCYTOMETER METHOD

This method of standardization was first used by Mallory and Wright.[12] They describe their procedure as follows:

> The chamber used is manufactured by Zeiss for counting blood plates by the Helber method. It should be supplied with an especially thin cover glass (No. 146 Zeiss' Catalogue) to permit the use of the high-power dry objective, with which the counting is made. The chamber is ruled like the "Thoma-Zeiss blood-counting chamber," and the rulings have the same value except that the chamber is 0.02 mm. deep instead of 0.1 mm. For counting, the suspension of bacteria is diluted and mixed with distilled water 1:200 with the aid of the red-blood-corpuscle pipet of the "Thoma-Zeiss" apparatus. By a simple calculation it will be apparent that the product of the multiplication of the average number of bacteria per small square by 4,000 million will be the number of bacteria per cubic centimeter.

This method was used also by Murray who, however, employed a common Thoma-Zeiss hemocytometer with a well 0.1 mm. deep, an ordinary cover slip which is not optically plane, a $\frac{1}{12}$ oil-immersion lens and a staining solution of weak Giemsa's stain.

Mallory and Wright's technic was the first employed by me, using, however, a diluent which stained the bacteria, and an ordinary 0.1 mm. deep hemocytometer. An aqueous solution of methylene blue was first employed. This was not found satisfactory, as there was insufficient contrast between the fluid and the bacteria. Aqueous solutions of carbol fuchsin and carbol thionin were later employed. The latter was found to be the most satisfactory of any yet tried. No definite depth of stain was used, as it was found that certain organisms required more stain than others. Usually 3 per cent. saturated alcoholic solution of thionin was added to 2 per cent. phenol in sterile distilled water.

[12] Mallory and Wright: Pathological Technique, Ed. 4, Philadelphia, W. B. Saunders Company, 1910.

Glynn *et al.* recommend the following as a diluting fluid:

Stock Solution A.—Saturated thionin-blue (Grübler) in absolute alcohol.

Stock Solution B.—1 per cent. of pure phenol in clear tap water.

Take one part of Solution A to about 40 of Solution B, for most organisms, or 1 part of A to about 20 of B, for streptococci.

Callison uses a fluid prepared as follows:

Hydrochloric acid	2 c.c.
Mercuric chlorid 1 to 500	100 c.c.

Acid fuchsin, 1 per cent. aqueous solution, enough to color.

Add the fuchsin until the solution is a deep cherry red.

This diluent possesses certain advantages over the others: 1. The bacteria are well stained and there is sufficient contrast to make them easily visible.
